INDEX TO VOLUME CXXXVI.

- Abbot, S. L.** Recollections of surgery before the use of anesthetics, 7; the stimulating treatment of pneumonia, 37.
- Abbott, A. C.** Further studies upon the pathogenic spirilla of the Schuylkill River at Philadelphia, 497.
- Abbott, S. W.** Report on progress in public hygiene, 309, 332.
- Abdominal Surgery.** Deductions from hospital work in abdominal surgery, with a report of forty-five cases, Johnson, F. W., 72, 61; two cases of laparotomy for acute intussusception, Warren, J. C., 125, 137; abdominal hysterectomy complicated with double ovariectomy: recovery, Pfeiffer, O. J., 131; a large abdominal tumor, Mixter, S. J., 190; the development of abdominal surgery during the lifetime of one man, 191; a case of numerous hydatid cysts disseminated in the abdominal and pelvic cavities, Farrar, 194; cases of gall-stone surgery, Elliot, J. W., 275, 287; an historical sketch of abdominal surgery, Chadwick, J. R., 429.
- Abel, J. J.** The chemical properties of the blood-pressure-raising constituent of the suprarenal capsule, 496.
- Achillodynia.** A case of achillodynia due to an exostosis of the os calcis associated with an interesting form of bursitis, Goldthwait, J. E., 515.
- Acromegaly.** Case of acromegaly, Osborne, 496.
- Actinomycosis.** Notes on actinomycosis, McIntire, H. B., 84.
- Adams, S. S.** The evolution of pediatric literature in the United States, 471.
- Adams, Z. B.** An epoch in medicine in an age of delusion, 557, 585.
- Allen, D. P.** The origin of appendicitis, 523.
- Anesthesia.** A bit of professional reminiscence, otherwise and otherwise, Cotting, B. E., 1; recollections of surgery before the use of anesthetics, Markoe, T. M., 2; recollections of surgery before the use of anesthetics, Ingalls, W., 5; recollections of surgery before the use of anesthetics, Abbott, S. L., 7; personal recollections of the first use of anesthetics, Galloupe, I. F., 8; personal recollections of the introduction of anesthesia, Bemis, C. V., 9; an incident in the early history of the introduction of sulphuric ether as an anesthetic, Wheeler, W. G., 9; surgical records of the Massachusetts General Hospital before 1816, Beach, H. H. A., 10; recollections of surgery before anesthesia, 19; the influence of anesthesia on the surgery of the nineteenth century, Warren, J. C., 423; the new local anesthetic, holocain, Derby, H., 540; an English account of the discovery of anesthesia, Leech, D. J., 610.
- Antisepsis.** Note on bismuthum tribromphenylicum as a surgical antiseptic, Cumston, C. G., 37.
- Antitoxin.** Behring's diphtheria antitoxin serum improved, 147; results of the use of diphtheria antitoxin, 292; the American Pediatric Society's report on the collective investigation of the antitoxin treatment of laryngeal diphtheria in private practice, 462; a collective investigation of the antitoxin treatment of laryngeal diphtheria in private practice, 473.
- Appendicitis.** Bicycling and appendicitis, 43; when to call a surgeon in appendicitis, Gay, G. W., 297; appendicitis in an infant, Taylor, F. W., 482; the origin of appendicitis, Allen, D. P., 523; perityphlitis and appendicitis in their relation to obstetrics and gynecology, Mundé, P. F., 518.
- Appleby, J. F. R.** Guaiac in puerperal eclampsia, 258.
- Army.** The library of the surgeon-general's office threatened, 118.
- Asthma.** The treatment of bronchial asthma, Knight, F. L., 273, 285.
- Bacteria.** Further studies upon the pathogenic spirilla of the Schuylkill River at Philadelphia, Abbott, A. C., 497; the effects of various metals and metallic salts on the growth of certain bacteria, Bolton, B. M., 497; the appearance of certain ameba-like bodies in the blood of vaccinated monkeys (Rhesus) and children, and in the blood of variola, an experimental study, Keed, W., 497; a bacteriological observatory in St. Petersburg, 582.
- Baker, F. H.** A report of three deaths from head injury, 327.
- Baker, L. W.** Southern Georgia as a winter resort, 271.
- Baldwin, H.** Thrombosis of the blood-vessels of the neck, 632.
- Barnes, H. J.** Railway car heating, 46.
- Bartlett, E. J.** A homicidal death from sulphate of strychnine, 570.
- Bartol, J. W.** Gavage in infants, 513.
- Baths.** The hygiene of swimming baths, 392.
- Beach, H. H. A.** The surgical records of the Massachusetts General Hospital before 1816, 10; gold foil in cerebral surgery, 281; anatomical specimens, kidney, 544.
- Beattie, H.** The use of digitalin with reference to the dose, 632.
- Behring's diphtheria antitoxin serum improved, 147.**
- Bemis, C. V.** Personal recollections of the introduction of anesthesia, 9.
- Benoud.** Paralysis of the posterior crico-arytenoids, 419.
- Berkley, H. J.** The psychical nerve cells of two educated men, 252.
- Berne.** Surgery under Kocher at Berne, 240.
- Bibliography.** Allbutt, T. C., a system of medicine, 413; Apathy, S., die mikrotechnik der therischen morphologie, 115; Bailey, J. B., the diary of a resurrectionist, 94; Bosworth, F. H., a text-book of diseases of the nose and throat, 212; Bourneville, recherches cliniques et therapeutiques sur l'epilepsie, l'hysterie et l'idiotie, 94; Buret, F., syphilis in the middle ages and in modern times, 67; Cabot, R. C., a guide to the clinical examination of the blood for diagnostic purposes, 577; Charaka Samhita, 394; Clarkson, A., a text-book of histology, descriptive and practical, 115; Corwin, A. M., essentials of physical diagnosis of the thorax, 67; Davis, E. P., a treatise on obstetrics, 67; Delafeld, E., and Prudden, T. M., a handbook of pathological anatomy and histology, 160; Dennis, F. S., system of surgery, 190; Deutsch's letters: a practical method for easy and thorough self instruction in the German language, 550; Einhorn, M., diseases of the stomach, 524; Gesundheitsbucklein, 140; Gould, G. M., the student's medical dictionary, 69, and the American year-book of medicine and surgery, 389; Gould, G. M., and Pyle, W. L., anomalies and curiosities of medicine, 576; Harvard Medical Alumni Association Bulletin, 240; Howell, W. H., an American text-book of physiology, 549; Huber, G. C., directions for work in the histological laboratory, 115; Hyde, J. N., and Montgomery, F. H., a practical treatise on diseases of the skin, 576; Impey, S. P., a handbook on leprosy, 68; Jackson, Edward, skiagraphy and its practical application to the study of retraction, 18; Johnson, G., the pathology of the contracted granular kidney and the associated cardio-arterial changes, 212; Keyes, E. L., the toxic treatment of syphilis, 18; Kirstein, A., autosepsy of the larynx and the trachea, 212; Loomis, A. L., Thompson, W. G., a system of practical medicine, 414; Lydston, G. F., over the hookah, the tales of a talkative doctor, 41; McFarland, J., a text-book upon the pathogenic bacteria, 166; McGillicuddy, T. J., functional disorders of the nervous system in women, 212; MacLagan, T. J., rheumatism: its nature, its pathology and its successful treatment, 413; Maynard, A. E., a treatise on the surgery of the alimentary canal, comprising the oesophagus, the stomach, the small and large intestines, and the rectum, 577; Michigan, twenty-eighth registration report, 446; Mosso, A., fear, 264; Musser, J. H., a practical treatise on medical diagnosis, 524; Paget, S., the surgery of the chest, 577; physician's visiting list, 1897, 18; Ransome, A., the treatment of phthisis, 68; Rockwell, A. D., the medical and surgical uses of electricity, 42; Saundby, R., lectures on renal and urinary diseases, 577; Schaeffer, O., anatomical atlas of obstetric diagnosis and treatment, 67, and essentials of gynecology, 556; Schweinitz, G. E. de, diseases of the eye, 68; Simon, C. E., a manual of clinical diagnosis by microscopical and chemical methods, 413; Spalteholz, W., hand-atlas der anatomie des menschen, 116; Stehman, T. L., modern Greek mastery, a short road to ancient Greek, 67, and twentieth century practice, 166, 114; Stevens, A. A., a manual of the practice of medicine, 524; Stohr, P., Text-book of histology, including the microscopical technique, 115; Thoma, R., Text-book of general pathology and pathological anatomy, 212; Thresh, J. C., water and water-supplies, 18; Treves, F., a system of surgery, 264; Turnbull, L., artificial anesthesia, 414; Tyson, J., the practice of medicine, 413; Unna, P. G., the histopathology of the diseases of the skin, 42; Wetterstrand, O. G., bryonism and its application to practical medicine, 550; White and Martin, genito-urinary and venereal diseases, 549; Witthaus, R. A., medical jurisprudence, forensic medicine and toxicology, 17; Wood, H. C., and Fitz, R. H., the practice of medicine, 115; Ziegler, E., a text-book of special pathological anatomy, 212.
- Bicycling and appendicitis, 43.**
- Biggs, H. M., and Prudden, T. M.** The segregation and supervision of tuberculosis, 74.
- Biography.** Abbe, E. P., 217; Agassiz, L., 145; Atwater, J. P., 547; Beaumont, W. S., 48; Blanchard, H., 172; Bolson, 339; Boynton, J. J., 640; Brand, E., 344; Bronson, J. O., 341; Bunker, E. S., 636; Burdett, G. W., 476, 524; Casella, L. P., 504; Charl., n., S. H., 196; Cooper, C. W., 148; Cotting, B. E., 528, 532, 554, 585, 637; Creamer, H. A., 216; Cushing, J. W., 475; Cushman, W. E., 476, 506; Dow, J. O., 220, 395; Dunlap, J., 555; Dusseldorf, O. L., 269; Eisenlohr, C., 420; Elliot, E. P., 48, 75, 121; Ethridge, J. A., 362; Feulard, H., 635; Fuller, A. J., 18; Fyfe, C. J., 316; Hall, R. J., 120; Hammer, C., 346; Hartshorne, H., 196; Herndon, J. C., 268; Huntington, H. K., 240;

- Johnston, W.** On the iodine test for semen, 321.
- Joints.** The treatment of disabled joints resulting from the so-called rheumatoid diseases, Goldthwait, J. E., 19, 32.
- Keen, W. W.** Address in surgery before the American Medical Association, 104.
- Keene, G. F.** General paresis, 221.
- Knapp, P. C.** Report on neurology, 88, 103.
- Knight, F. I.** The treatment of bronchial asthma, 273, 2-5.
- Knowlton, H. M.** On the duties of a medical examiner, 321, 335.
- Koch's new tuberculin**, 415.
- Kocher.** Surgery under Kocher at Berne, 240; Kocher's views of gonorrhea and cretinism, 657.
- Labordes.** The Labordes method of resuscitation, 98.
- Lancet.** Curious statements in the *Lancet*, 171.
- Laparotomy.** Two cases of laparotomy for acute intussusception, Warren, J. C., 125, 137.
- Larabee, H. C.** The sterilization of catgut by boiling alcohol, 86.
- Larynx.** A case of cancerous degeneration of a laryngeal papilloma following operation, Goodale, J. L., 58.
- Leech, D. J.** English account of the discovery of anesthesia, 410.
- Legal Medicine.** Recent progress in legal medicine, Iraper, F. W., 184; on the duties of a medical examiner, Knowlton, H. M., 321; on the iodine test for semen, Johnston, W., 321; a report of three deaths from head injury, Baker, F. H., 327; the identification of seminal stains, Whitney, W. F., 329; on the duties of a medical examiner as a witness, Boat, S., 330.
- Levant fever**, Smith, A. A., 498.
- Lister.** Pathological research and humanity, 194.
- Lithemia.** The treatment of lithemia, Rachford, A. K., 493.
- Locke, P. S.** The use of Ringer's fluid, 243.
- Loomis sanitarium for consumptives**, at Liberty, 634.
- Lothrop, H. A.** Hernia epigastrica, with a report of cases, 175, 185, 200; empyema of the antrum of Ighmore, 455, 465; a case of hypospadias, 541.
- Lovett, R. W.** The prevention of flat-foot and similar affections, 137; the treatment of sprains, 594.
- Lumbar puncture**, Wentworth, A. H., 107.
- Lund, F. B.** A case of web-fingers, associated with curious anomalies of the phalanges, metacarpal bones and finger-nails; with kinagram, 157; the treatment of old dislocations of the shoulder, 397, 409.
- Macdonald, W. G.** Public health in Rome, 121; public health in Vienna, 528.
- McIntire, H. B.** Notes on actinomycosis, 84.
- McPhedran, A.** Pancreatitis followed by cyst of the pancreas, 492.
- Malaria.** A case of congenital malaria, Winslow, K., 514.
- Mann, M. R.** Intra-abdominal shortening of the round ligaments for posterior displacements of the uterus, 574.
- Manser.** The respiratory form of plague, 553.
- Marcy, H. O.** The cure of hernia, 381, 388.
- Markoe, T. M.** Recollections of surgery before the use of anesthetics, 2.
- Martin, E.** The mortality of intussusception, 218.
- Mason, A. L.** Gall-bladder infection in typhoid fever, 449, 468.
- Massachusetts.** The report of the commission on the public charitable and reformatory institutions of the Commonwealth of Massachusetts, 265; resolutions of the Boston Medico-Psychological Society on the report of the commission to investigate the public charitable and reformatory interests and institutions, 295.
- Massachusetts General Hospital.** The surgical records of the Massachusetts General Hospital before 1846, Beach, H. H. A., 10; clinical meeting of the staff, 374; eighty-third annual report of the Massachusetts General Hospital, 608.
- Materia Medica and Therapeutics.** A note on bismuthum tribromophenylum as a surgical antiseptic, Cumston, C. G., 37; Behring's diphtheria antitoxin serum improved, 147; eucain as a local anesthetic in ophthalmic surgery, 195; the use of Ringer's fluid, Edes, R. T., 219, Locke, F. S., 243; guaiac in puerperal eclampsia, Appleby, J. F. R., 278; discussion on stimulation in a uterine diseases, Wood, H. C., 289; results of the use of diphtheria antitoxin, 292; veratrum viride in puerperal convulsions, Thayer, W. H., 29; chloroform in labor, Hall, J. N., 367; Koch's new tuberculin, 415; the treatment of pneumonia and of influenza by large doses of digitalis or digitatin, 445; a further study of some of the untoward effects of the bromides, Hare, H. A., 499; the new local anesthetic, holocain, Derby, H., 549; the use of digitatin with reference to the dose, Beattie, H., 632.
- Maternal Impressions.** Remarks on maternal impressions, Councilman, W. T., 32, 41.
- Mays, T. J.** Increase of insanity and consumption among the negro population of the south since the war, 537.
- Medicine, sorcery, witchcraft, spiritism in the middle ages**, 391.
- Meirowitz, P.** Compression of spinal cord by a hydatid cyst, 64.
- Milk.** The home modification of milk, Morse, J. L., 230.
- Mind.** Mental automatism in epilepsy; a psychological study, Clark, L. P., 29; a case of "imperative idea" or "homicidal impulse" in a neurasthenic, without hereditary taint, Prince, M., 57; the prognosis and duration of attacks of mental disease, Stedman, H. K., 566.
- Minot, J. J.** A case of septicemia of obscure origin, 230.
- Mitchell, L. T.** A fatal case of poisoning by red oxide of mercury; necropsy, 257.
- Mixer, S. J.** A large abdominal tumor, 190.
- Montgomery, E. K.** Pelvic blood-collections and their treatment by vaginal incision, 575.
- Morse, J. L.** The home modification of milk, 230; a study of the blood in rickets, 369.
- Mumford, J. G.** Stercoral ulcer, 139; the treatment of sprains by massage, 595.
- Munde, P. F.** Perityphilitis and appendicitis in their relation to obstetrics and gynecology, 548.
- Murray, R. A.** The treatment of syphilitic women in pregnancy and parturition, 548.
- Music.** The musical faculties in health and disease, 238.
- Musser, J. H.** Angina pectoris, its relation to dilatation of the heart, 492.
- Negro.** Increase of insanity and consumption among the negro population of the south since the war, Mays, T. J., 537.
- Nervous System.** Mental automatism in epilepsy; a psychological study, Clark, L. P., 29; excessive physical exercise as cause of nervous exhaustion, Welber, S. G., 34; a case of "imperative idea" or "homicidal impulse" in a neurasthenic, without hereditary taint, Prince, M., 57; a case of acute multiple neuritis or anterior poliomyelitis, with involvement of the face, Stieglitz, L., 143; compression of spinal cord by a hydatid cyst, Meirowitz, P., 64; the pathology and treatment of migraine, Herter, C. A., 64; report on neurology, Knapp, P. C., 88, 103; insolation, Jackson, H., 101, 111; lumbar puncture, Wentworth, A. H., 107; recent advances in neuropathology, 167; cases simulating syringomyelia, Hammond, G. M., 210; cerebellar ataxia, Jacoby, G. W., 210; demoniacal possession, James, W., 210; general paresis, Keene, G. F., 221; the psychical nerve cells of two educated men, Berkley, H. J., 252; cerebrospinal meningitis, a disease dangerous to the public health, 337; the anatomical nomenclature of the nervous system, 416; paralysis of the posterior crico-arytenoids, Benoud, 419; a case of nervous deafness in diphtheria, Wilson, J. C., 494; the relation of neurasthenic conditions to the general nutrition, Edes, R. T., 495; the reflex neuroses of the abdomen, Bridge, N., 496; report of a case of removal of the gasserian ganglion, Weeks, S. H., 522; the technique of cranial surgery, Tilly, L. M., 523; a case of brain cyst with Jacksonian epilepsy, operation followed by relief, Cabot, A. T., 533; cyst of the brain, Elliot, J. W., 539, 544; relation of neurasthenic symptoms to the general nutrition, Edes, R. T., 589, 617.
- New Hampshire.** Medical registration in New Hampshire, 270.
- New Zealand.** The rates of mortality in New Zealand, 20.
- Nichols, E. H.** Anatomy of congenital equino-varus, 150.
- Noble, C. P.** The history and present status of hysterectomy for fibroid tumors of the uterus, 546.
- Nomenclature.** The anatomical nomenclature of the nervous system, 416.
- Nurses and nurses.** 213, trained nurses and the public, 394.
- Observatory.** A bacteriological observatory in St. Petersburg, 582.
- Obstetrics.** Recent progress in obstetrics, Townsend, C. W., 132; some things I was not taught in obstetrics, Boland, E. S., 254, 261.
- Orthopraxy.** Anatomy of congenital equino-varus, Nichols, E. H., 150; report on orthopedic surgery, Bradford, E. H., and Brackett, E. G., 158; value of mechanical exercise in the treatment of stiffness of the joints, Bradford, E. H., 163; the direct transposition of muscles in the correction of deformities, Goldthwait, J. E., 163.
- Osborne.** Case of acromegaly, 466.
- Osler, W.** The hepatic complications of typhoid fever, 469.
- Otis, E. O.** Are especial hospitals or houses for consumptives a source of danger to their neighborhood? 395.

A BIT OF PROFESSIONAL REMINISCENCE,
ETHERWISE AND OTHERWISE.

BY BENJAMIN EDDY COTTING, M.D., A.M., A.A.S., ETC.
Ex-President Massachusetts Medical Society; Assistant at the first Public Demonstration of Sulphuric Ether for annulling Pain during a Surgical Operation at the Massachusetts General Hospital, October 16, 1846.

MY FIRST CASE AFTER GRADUATION.²

IN the autumn of 1837, having previously taken my medical and other degrees at Harvard University, and having joined the Massachusetts Medical Society — then, as now, the two essentials for one intending to become a regular physician in Massachusetts — I took an office in Boston, temporarily, that I might again hear medical lectures, walk the hospital, occasionally attend a dispensary-patient, and, having no ambition to become a city doctor, that I might more easily find, as at length I did find, what I most hoped for, permanent residence in a reasonably large suburban country-town.

A few days after I had taken my room, I unexpectedly received a request to visit a middle-aged gentlewoman — in order, as I supposed, to assist in a charitable enterprise in which I knew her to be interested. I found, however, to my surprise, that she wished professional advice. Her ailment proved to be a mammary scirrhus infecting the entire organ, and apparently ready to break out externally into a cancerous ulcer. As gently as I could, I suggested that the whole organ must be removed without delay. Such was the practice then, and may be now, though it has varied much in the interval. On rising to leave, I was asked to consider the visit as strictly professional, and to make note of it, as she would probably wish to call me again. I left gratified, but somewhat astonished.

A few weeks later, she sent for me again; in the mean time she had consulted Drs. Warren and Hayward and other eminent surgeons and older medical men, and had received, presumably, similar opinions and advice. On my arrival this time, she took me into her parlor, and having locked the door, approached me with upraised finger and said in earnest and solemn tones, "I do not ask you to say whether you can do the proposed operation as well as the eminent men I have consulted; but I do ask you to tell me plainly, *upon your honor*, whether you think you can do it *well*."

On my admitting, calmly as I could, that I did think I could do it *well*, she told me to come early the next week and perform the operation.

Now, here was a trying situation for a young practitioner with his first notable patient. Friends, especially young professional friends, and some older ones, strongly urged me not to attempt so serious a matter, suggesting that, leaving out the possible return of the disease with ultimate fatal result, there was the possibility of imperfect performance, the risk of loss of self-possession in case of unexpected emergencies, and other like chances. Dr. Hayward alone emphatically said, "Of course you'll do it — and I will be present to render any needed aid!" In truth, I had already, while a student, performed quite a number of severe surgical operations in almshouse practice, some of magnitude, severity and danger, quite equal to that

proposed; and therefore hesitated less than if it were a first trial. Besides, I intended to, and did actually, repeat dissections and perform this operation on the subject to further qualify for this occasion.

Well, the day arrived. Four physicians, Drs. M. S. Perry, Wiley, Carpenter and Wellington, came as assistants (to hold the patient); and Dr. Hayward, true to his word, was there also.

The patient — never one of more self-possession or of greater self-control — was afterwards said to have involuntarily struggled forcibly, and to have groaned vociferously, fearfully affrighting all in the house. The operator, however, proceeded, unmiudful, as was his duty, of the struggles, and literally deaf to the groans, and rapidly finished the amputation. Dr. Hayward managed the sponges and tied the arteries, a half-dozen or so. The bleeding was considerable, but not excessive. The cutting portion had taken but a few seconds; rapidity was then as essential as dexterity.

The arteries were tied, and in tying the arteries one string was cut off close to the knot, and the other brought down and out at the nearest convenient place, for easy removal later, and to guide to the surface slight oozings, if any; then, the arteries tied and the wound wiped dry, the integuments were brought over the cut surface, and secured at their edges by two very small superficial stitches of thread, except at one point where the skin involved in the disease had been removed; here the wound was left to granulate. Then a layer of old-fashioned sheet-lint, suitably shaped, laid over the whole wound. Over all a soft compress to support the parts was secured from above downwards by a soft roller bandage. Such were the simple dressings — the usual ones — in those days. Household nursing, more valued then than now, accomplished the rest to perfection.

This patient "did well," as the phrase is. There was no after-hemorrhage, hardly a drop of oozing, no constitutional disturbance to speak of; the dressings were gradually removed (by daily clippings), and new supplied as needed. The ligatures all came away within four or five days, without resistance, and the wound healed by first intention, throughout, except at the small excised portion, which granulated normally and healed rapidly.

The operation was satisfactory to all parties. In less than a fortnight the patient was about the house; and before the season was over she was engaged in her usual avocations and in society as a well woman. The disease never returned.

Such was surgery in the hands of an ordinary medical man sixty years ago; for this operation was performed nine years before the discovery of anesthesia. Other cases were like unto it; for this was merely an ordinary case — only remarkable that it fell to a young beginner, so early in his career, and perhaps in that it was successful, by chance, on many of the points which have since been too unequivocally attributed to new processes in detail. Certainly Nature sometimes seems to favor the uninstructed and inexperienced, and fortunately does the healing for them.

But what of the patients? one may ask. No mortal man can ever describe the agony of the whole thing from beginning to end, culminating in the operation itself with its terrifying expressions of infernal suffering.

Our patient in the above related case writhed beyond

¹ Gallieé for looker-on.

² Suggested by the papers presented at the Ether Memorial, written for, and read at the request of the manager, on the second or adjourned day of the Memorial, December 9, 1896.

the restraining power of strong and experienced men, and groaned, to the horror of the terrified household; and afterwards, to the day of her death, could not think of the operation without convulsive shudders. Often did she hold up her hands, exclaiming, "Oh, that knife! that awful knife!! that horrible knife!!!" Even on her death-bed, to which she was brought years later by another and entirely different malady, she more than once raised her wasted and enfeebled hands and faintly gasped the same words.

From one case learn the whole story: they were all alike, full of dreaded horrors to patients, and not without terrors to operators.

The ether discovery is *the* discovery in medicine — nothing like it before or since, and probably never will be. But it is fast becoming a thing of the "old time," and is now already out of the half-century, asserted to be so exclusively filled with all the good things.

Of course, anesthesia is the "great thing" of the age, or of any age; its benefits, however, should deter us from needlessly underrating and smiling at the shortcomings of our forefathers. lest we be laughed at for our own unbounded pretensions by those who shall come after us, and that, too, within less than another fifty years?

Soon after the ether discovery I performed a similar operation for a patient who declined to take ether; she knew she could bear it without flinching, and did not wish to have her mind clouded or her senses benumbed. The first cut—a rather long one—was borne pretty well; but the second was too much for her. She raved and stormed, roared out heavy groans and heart-rending shrieks. The operation would have had to be abandoned had not sufficient muscular force been provided for, quietly, in advance. She was held during tetanic-like spasms, and the operation was completed while she was in a position, almost that of opisthotonus. Her outcries aroused the neighbors, who rushed in in numbers to know what the occasion might be. In due time she recovered. But she never ceased to regret her mistake. Her case was often used in advocating anesthesia, and did much to establish the administration of ether in the neighborhood.

In perfect contrast to this case, I removed for another patient a large mammary tumor, under ether, and when, a year or two later the disease began to return, she insisted upon a second operation, which subsequently she required to be repeated a third and a fourth time. She declared that she would rather wake up out of unconsciousness into the knowledge of a larger but healthier and less painful wound; but at last, when after several years, apparently gained by the operation, and there being nothing left but exposed ribs and intercostals, and these beginning to show disease, she quietly settled down into a contented resignation to her fate. Ether had certainly given her several years of comparatively comfortable life.

As we left the amphitheatre on October 16, 1846, one of the foremost of the younger men called to me (by surname without prefix) saying: "If you get anything new on this matter please let me know it at once. This is a *big thing*. Whoever gets astride of this horse *first*, may ride around the world! I'm going to try it." And he *did* try it effectively; and if he at a later date more notably completed the circuit, his royal progress was due as much to his own special achievements in surgery as to the speed of the particular nag he then mounted.

I associated much with the first experimenters of etheric anesthesia. Its first days did not pass as smoothly as now thought. There were sceptics who declared the whole thing a sham, a hazardous humbug. "They'll kill somebody yet," was the frequent prediction. The discoverer was persecuted in every direction. Having had as a patient a hysteric young woman who went into convulsions on inhaling the ether, he was summoned into a criminal court to answer to the charge of malpractice; and, had this been his first patient, no one would have dared repeat the experiment, or allowed it to have been made, and the world would have lost its greatest boon. By such a narrow chance did the discovery escape failure. Threatenings were rife, and the public was greatly agitated against the then-called reckless experiments. But some strong men were convinced and outspoken. Successful results were too numerous and overwhelming. The facts were soon widespread, and everybody resorted to the practice when needful.

The envious declared that such a discovery was too great for any one man to have the credit of. "Providence never intended such a glorious honor for any one individual," said they; and immediately set about relieving Providence from any such imputation.

Fortunately, the mills of time are slowly grinding out the truth in these matters, and the crown is gradually and securely resting on the head of the real discoverer.

RECOLLECTIONS OF SURGERY BEFORE THE USE OF ANESTHETICS.¹

BY T. M. MARKOE, M.D., NEW YORK.

WHEN the proposal to use anesthetics in operations began to be discussed in the surgical professional world, it soon became evident that there were two opinions on the safety, availability and wisdom of the measure. One party, mainly comprising the younger men, was warmly, even enthusiastically, in favor of giving the plan a trial, and the other, embracing many of our best and most eminent practitioners, felt hesitation as to its expediency, and some even opposed the proposal as dangerous and unjustifiable. The opposition contended that, in the first place, the prolonged etherization was a menace to life in itself, some cases having been reported, in which death had been directly due to the effect of the anesthetic, independent of operation or manipulation. Secondly, it was thought that, as the whole nervous system was under the paralyzing influence of the anesthetic, the circular coats of the vessels would lose their contracting power, and that, by reason of this want of contracting power, the blood-vessels would not retract and contract, as we usually observe them to do after section, and that therefore there would be much more active and less manageable hemorrhage than there would be if the nerves retained their sensibility. Thirdly, it was suggested, that, after the depressing effect of the anesthetic, and the nervous and stomach disturbances following its administration, the reparative processes would be less prompt and less perfect than they should be and that therefore primary union would be more rarely attained, and that suppuration would be a common result, even after the most trifling incision.

¹ Read before the Clinical Meeting of the Staff of the Massachusetts General Hospital, December 1, 1896.

It will hardly be realized in our day how warmly these questions were then discussed, nor is it necessary, in the light of our abundant experience, to point out their fallacy. It is quite enough for us to know, that death from ether, when properly administered, is so rare that its occurrence may be practically excluded from our consideration; that wounds inflicted under anesthesia do not bleed any more and are in no sense less manageable than those inflicted without the paralyzing effect of ether; and that the condition of wounds after anesthesia compares in all respects favorably with that of those which have been made without the disturbing effects of ether.

The question is often asked, What did surgeons do to mitigate the sufferings of operation before the discovery of etherization? Practically they did nothing. Various attempts were made in that direction. Cold was applied, by various refrigerating processes, to the point of benumbing the parts, care being taken to stop far short of congelation; but all these trials had the fatal defects that they could not be maintained during the operative procedure, and that they only affected the surface of the wound, any excursion of the knife into numb parts giving pain. Opium naturally was suggested, and was very frequently used; but while its power of soothing pain after operation was recognized, its power of preventing pain during operation was disappointing. In short, up to the time of etherization, I think it may be said that, for preventing, or even diminishing, the pains inflicted by the surgeon's knife, there was no system or plan which had any general acceptance or was generally employed for that purpose, or was even moderately effective.

It has been generally supposed that, when patients were being operated upon without ether, it was necessary to bind them with straps or cords, to prevent them from making such involuntary movements as might seriously interfere with the surgeon's manipulation, and perhaps lead to serious if not fatal accidents. As a general rule, no such precautions were found necessary. Of course, in certain operations, as those in the perineum and those in the axilla, the legs in the one case, and the arm in the other, had to be maintained in a certain position, in order that the organs or parts to be operated upon might be made and kept accessible to the surgeon's knife. This, however, was only to secure a proper position, and not at all to prevent muscular resistance on the part of the patient, and, as a matter of fact, it is even now adopted, while the patient is under the full effect of ether. With children, and with certain over-sensitive, excitable, and uncontrollable persons, it was at least prudent to be sure that no sudden and perhaps involuntary movement on the part of the patient might interfere with the surgeon's proceedings; but this was never accomplished by mechanical restraint, but only by the watchful hands of a sufficient number of reliable assistants. Indeed, it almost seemed as if a certain instinctive consciousness of the danger of muscular movement or resistance restrained the sufferer from trying to escape from his tormentor, lest, perhaps, any unexpected movement by him should cause trouble and perhaps danger.

With regard to the operation itself, a great difference among individuals could be noticed as to their courage and fortitude in bearing pain. The great majority showed their suffering by groans or cries of

more or less intensity, which they seemed to have no power to control, and which indeed seemed to afford a sort of relief to their sufferings. In this respect, all agreed that women bore themselves more courageously than men; or rather, perhaps it would be more proper to say, that instances of superior fortitude and endurance were more common among women than among men; and in some of these heroic cases a long and severe operation was borne without a cry or a tremor of voice or muscle. But these were, unfortunately, rare cases, and in most the expressions of suffering were loud-voiced, and to a novice most distressing. A curious effect of the unrestrained screams and groans of those being operated upon was seen in its result upon the students in the operating-theatre. In November and December, when the young men began to assemble, to begin their course at the college, many of them attended the operations at the hospital, and there witnessed for the first time a surgical operation. It often happened, so often that preparations were systematically made beforehand, that one at least of the students watching the operation would begin to turn pale, and then faint, and presently would sink down in his place, if not supported by his comrade sitting by him. The nurses and attendants were instructed to watch for any manifestations of faintness in any of the boys, and to immediately remove them from the theatre and place them on a bed with the head low, and leave them to recover. This became so much a matter of routine, and all parties became so familiar with the scene, that it created no disturbance, and the operation or lecture went on without any confusion or interruption. It is true that this happened only in the first few weeks or months of the session, before the boys had become accustomed to the bloody scenes; but the fact remains that since the advent of anesthesia such acclimatization has been unnecessary, and that such fainting and carrying out is rarely observed, even in novices, witnessing for the first time the most severe and bloody operation. This can only be accounted for on the theory that the cries and groans and other manifestations of suffering produced a more powerful impression on the unaccustomed spectators than even the most extensive and bloody proceedings of the surgeon, and that these expressions of pain being excluded by the anesthetic, the trying effect of the spectacle is reduced to a minimum. However we may explain it, the fact remains, and it is a curious memento of pre-anesthetic days. This effect of the expression of surgical suffering on the bystanders is perhaps of no great importance in itself; but may it not be asked, What was the effect on the surgeon himself? Could he be as cool and deliberate with a patient writhing and screaming under his incisions as he would with one completely insensible to pain? Would he always be able to be as careful and thorough in one case as the other? The answer would seem to be that, while the experienced and conscientious surgeon would not, in such a case, be influenced to shirk any part of his duty, the neophytes, the timid, and the over-sensitive might sometimes be induced to hurry their cases, and get rid of trying complaints as soon as possible at the risk of overlooking or neglecting some of the minor details, on which so much of the comfort and often the safety of the patient sometimes depends.

One instance of fortitude and endurance which excited no little admiration and some amusement oc-

curred in a case in which Dr. I. K. Rodgers was operating on a very extensive necrosis of the tibia, in a fine, manly looking sailor, whose whole demeanor showed that he had come to the operating-table determined to accept and endure whatever pain it was deemed necessary to inflict upon him. He bore the first incisions without a murmur, but when the tedious and painful process of stripping the integuments from the face of the involucrum had been going on some little time, he turned to one of the assistants, and asked in a whisper, "Could I have a chew of tobacco?" It was given him, and seemed to comfort him and brace him up, and the operator proceeded to the chiselling of the bony covering of the sequestrum, which was an unusually long one. This exasperating infliction of hammering and chiselling went on for a while, when the patient asked again for another chew of tobacco, which was given him; and as before it seemed to reanimate his courage. The chiselling was long and tedious, and the poor fellow turned once more to the doctor and said, "Doctor, doctor, give me another chew of tobacco, and give me a damned big one this time." This was done, and under the stimulating influence of a "damned big chew," the operation was completed, having occupied the best part of an hour, during which not one word of complaint was uttered and not even a groan passed his lips. It should here be noticed, that many patients seemed to suffer more by the manipulations, which, after the main steps of the operation were completed, are necessary to be carefully attended to. Each touch of the sponge was a separate pain, and the ligature of each vessel seemed to give an acute pang. If the vessel were large enough to be pulled out of its sheath and isolated from surrounding tissues, its ligature seemed to be painless, but when the smaller vessels were taken up with the tenaculum, including some of the surrounding nerves and muscular fibres, the pain was extreme; and this having to be repeated many times, became from its repetition a severe tax on nerves already sorely strained by endurance of a long operation. What seemed, however, the most trying of all these minor manipulations, was the introduction of the sutures. The prick of the needle first through one lip and then through the other, and this repeated until eight or ten or more sutures were introduced was so hard to bear that few could restrain their impatient cries, though they might have behaved heroically during all the previous tortures of the operation.

The question, How much is the shock of a severe operation diminished by the insensibility of anesthesia? is one about which statistics do not give us any very positive answer. But the answer of every one of large experience is unequivocally in the affirmative, and to a very large degree. The fright, the appreciation of danger, the anxiety as to result, which the patient feels before the operation, with the section of nerves and the loss of blood during the operation, must necessarily be in themselves a cause of depression of the vital forces; but when you add to these the pain and terror which the progressive steps of an operation inspire, it would be safe to say that you have added the most potent of all the elements of shock, and further, that by eliminating these powerful factors you have very greatly diminished the dangerous features of shock, though you may not have removed them all. Certainly this is the verdict of the most experienced and trustworthy of practitioners.

Another point should not be overlooked. The fact that the patient is relieved from all apprehension of pain, either in diagnostic exploration, or in the operation itself which is in consideration, is a reason why he will be more ready, and will submit much earlier to the exploration or to the operation, thereby improving the chances of diagnosis and of operation, and sometimes of avoiding that saddest of all surgical verdicts, "Too late." How often that verdict had to be given in those pre-anesthetic days, every man, in large practice, had too many opportunities to record.

Speaking of exploratory manipulations for purposes of careful diagnosis leads us to notice the immense advantage which we have over the fathers, not only in the readiness of the patients to submit to such explorations, but in the deliberateness and thoroughness with which they are now made under ether. In those days, the examination of a tight urethral stricture, or of a bladder suspected to contain a stone, or of a rectum suspected to be cancerous, and in which the question to be settled was whether the diseased tissues were within the reach of the surgeon's knife, all these were as much dreaded, and gave sometimes almost as much pain as the operation they indicated. With all this dread and suffering from the mere examination, is it likely that the conditions should be as thoroughly and carefully explored as we explore them now, under the comfortable insensibility of ether? And if not thoroughly diagnosed before operation, is it not probable that many mishaps may have occurred during, and many failures after, an operation undertaken with an imperfect or erroneous conception of the diseased conditions which the operation was intended to remove.

There remains one department of surgery in which the advance from pre-anesthetic methods is most striking and important, and though not covering a very extensive field has, nevertheless, in that field developed some of the most valuable results which have been achieved in the whole anesthetic story. I allude to that class of cases in which the surgeon's efforts are antagonized by the involuntary, and indeed sometimes by the voluntary, action of muscles, which muscular antagonism it is often of the first importance to overcome, and in which failure to overpower the muscles often means failure of the manipulation which the surgeon has undertaken. This class embraces all those cases in which muscular contraction interferes with the surgical procedure, as in operating on the eyeball, on the throat, on the rectum, and some others, where the surgeon's work lies in the midst of muscles whose every contraction interferes with his procedures and not infrequently defeats them. Perhaps the best illustration of this class of cases is found in the reduction of dislocations, or the replacement of fragments in complicated and obscure cases of fracture. Here the main obstacle to success is muscular resistance, and it constantly happens that this resistance being overcome, the replacement becomes prompt and easy. It is therefore to the overcoming of the resistance of the muscles that we look to secure success; and in proportion to our control of muscular action is that success likely to be achieved. Three methods were resorted to in pre-anesthetic days to obviate muscular resistance. These were, first, bleeding *ad deliquium*; second, the use of tartrate of antimony; and, last, the use of tobacco as a rectal injection. These were used to the extent of producing a depression and relaxation of all

the vital forces, in which depression, of course, the muscular system largely participated; while thus relaxed the replacing efforts were made, and it must be acknowledged that something was gained and some replacements easily accomplished. But it was noticed that however faint and relaxed the patient might seem to be, as soon as the first attempts at reduction were made, the muscles were excited to resistance, and it soon became evident that we had not removed but only diminished the resistance which we desired to abolish. While consciousness remained, and the spinal reflexes were not abolished, no method we were acquainted with would altogether prevent muscular resistance; and sometimes, to our chagrin, the harsh and spoliative methods above mentioned, proved perfectly unreliable and unsuccessful in the very cases where we expected most from them. It is only when we compare the ease and promptness with which, under ether, we now reduce by manipulation alone a dislocation of the femur or shoulder, with the former laborious, tedious and painful efforts with pulleys and straps, that we fully appreciate the great blessing of anesthesia in enabling us to abolish all opposition from muscular action in the class of cases now under consideration. It seems as if we might fairly say that anesthesia, in this class of cases, is the most direct and positive addition to our surgical resources that the century has produced. For while all heartily concur in glorifying anesthesia as the annihilator of pain in surgical operations, in no department can it claim so direct a share in the success of the surgeon's efforts as in this, and in none does it form so essential a part of the successful procedure.

In conclusion, I cannot refrain from relating a circumstance in this connection which gave us no little anxiety and annoyance during the reduction of a luxation of the hip, but which caused us all to smile when the procedure was over. During my term in the hospital we had come to rely for the relaxation of resisting muscles, on the introduction into the rectum of a small but strong infusion of tobacco. This usually produced its effect in a few minutes, and was commonly followed by a depression and relaxation which was eminently favorable to our purpose; but the reduction being accomplished, perhaps, in a few minutes, the action of the tobacco continued for an hour to affect, and sometimes very seriously to depress the patient. We had come, therefore, to the plan of introducing into the rectum a cigar, instead of the more rapid and abiding infusion. This cigar had a string tied around its big end to enable us to withdraw it, and then being dipped for a moment into hot water was introduced by the small end into the rectum. The object of this plan was to enable us to remove the tobacco as soon as we had no longer any occasion for its effects. The case in question was that of a man with a dislocation of the femur, in which the pulleys and counterextending bands being all prepared, the cigar was introduced as usual, and we waited a few minutes for its effect. No relaxing effect was observed, however, and after waiting a suitable time, the reduction was effected by main force, to the great disgust of the surgeon and with terrible sufferings by the patient, no effect having been produced by the tobacco before, during or after the reduction. Of course, the cigar was then removed, and the cause of its ineffectiveness was made clearly manifest. The young dresser to whom had been con-

fided the introduction, not finding it easy to push it through the anus, had oiled it liberally, and thus succeeded in lodging it within the rectum. The mystery was solved; and henceforward it was decided that if any lubricator was to be used in these cases, mucilage should be preferred to oil.

RECOLLECTIONS OF SURGERY BEFORE THE USE OF ANESTHETICS.¹

BY WILLIAM INGALLS, M.D., BOSTON.

IN response to your courteous note, asking me to give you my recollections and impressions of the introduction of ether as an anesthetic, and of the times preceding, I cheerfully comply, asking you to bear in mind that I am not attempting an essay, but am offering my thoughts as they occur, and begging, therefore, your habitually lenient criticism for them.

I returned to Boston in 1847, after an eight-years' absence in Louisiana, where I practised among the plantations of West Feliciana. During this time, I had but few opportunities of meeting members of the profession; thus I suffered for the want of professional pabulum, which was scantily supplied by medical letters and journals only.

During the few months between my receiving the news of the first administration of ether and my arrival home, particularly during my long sailing voyage, I mused and pondered, and hoped—hoped with an earnest longing that I would find it true, that I should find it to be a fact that a substance had been discovered which would prove to be triumphant over pain, and which would overcome the horror and dread of the surgeon's knife.

Can it be true, I thought, that we now have the power to abolish those scenes of suffering with which I, in common with my *confrères*, am only too familiar? Although the surgeon, previous to operation, rarely failed to propose every means that his judgment and hope might suggest, to lessen the coming infliction, yet the infliction often remained a dreadful one, where efficient assistance was often lacking, the patient rebellious; where fears were to be overcome and merciful counsel offered; and where, often in spite of all that promised alleviation, the surgeon was obliged to operate upon a screaming and writhing being—to feel an almost equal strain upon his coolness, while conscious of the evidences of suffering, the clutched hands, the grinding of the teeth, the sharp catching of the breath, even from those who had the courage to suffer in silence.

Allusions to surgical occurrences in pre-ether times being made, permit me briefly to enlarge upon them.

The fortitude of some women, as well as men, was oftentimes a subject of pitiable admiration. The custom was to give opium or whiskey previous to operations. There were those who would say, "If you think best, I will take what you offer me, but I've made up my mind to go through with what is necessary, and I am ready without it." We have been told by many who have had the experience of a surgical operation, that the first incision, the cutting of the skin, was the most painful of all; and I have been amazed when some subjects under the knife have lain still, uttering no cry; but there was no deception as

¹ Read before the Clinical Meeting of the Staff of the Massachusetts General Hospital, December 1, 1896.

to suffering. One sees the hands tightly closed or strongly grasping a friend's, holding the breath with occasional noisy exhalations; one longs to hear loud outcries, they being the natural expression of pain.

The method of guarding against movements or struggles was intrusted to the care and watchfulness of attendants; I do not recollect any case for which swathes were used.

It is admitted that the observations of any one person do not amount to much in the elucidation of general subjects; and when their record is made, which overturns preconceived ideas, it is apt to be received with some misgiving as to its truth. Something may, however, be gained from a brief record of a few cases which I hold in remembrance as clearly as though they occurred yesterday:

In the year 1825 I assisted my father while he applied a first dressing to a compound comminuted fracture of both bones of the left leg of a youth; that is, I obeyed explicit directions. This was my first surgical observation. In reply to my question, why the patient did not cry out, or give more tokens of suffering than he did during the manipulations, I was told that there seemed to be, for a time, a dulling or an obtunded condition of the nervous system, after severe injuries. We call it "shock."

About three years after this, I had the privilege of being present at an operation for the extirpation of a tumor on the back of an elderly woman, who, at the first incision, gave a loud scream; her whole body seemed to shrivel; after which there were groans and moans, but there was no struggling. There were five elderly women, all of whom expressed themselves ready and willing to assist. In a little while, one of them quietly slipped through the door; shortly after, another; finally the operator and myself alone were left.

These two cases occurred in time of vacation, which accounts for the absence of students, or other and competent assistants; and it may be mentioned that, in those days, there was not a multitude of students and medical friends to select from for assistance.

I recite a more recent case which is typical of several others of former days: In 1877, a woman of large frame, beyond the menopause, developed cancer of the left breast. After due deliberation and consultation, it was decided that an operation was necessary. Upon announcing the decision, the first words she uttered were, "Not under ether." Every argument, professional, friendly, filial, that was used to induce her to accept the administration of ether, was of no avail. During the operation, so far as any movement of the body or limbs was concerned, my two or three assisting students had literally nothing to do; the patient's right hand was strongly grasped in that of my good friend and consultant. From the first moment of incision until she was placed in bed, there was no second of time in which she was not reviling me for brutality, for being without mercy, for not taking heed of the agony I was causing; and these cries rang in my ears for many days. It was like a refusal to drink from a clear, cool spring, while perishing with thirst.

I can see here in this old amphitheatre now, the left clavicle dissected out by Dr. Warren in 1831. Here and elsewhere, I have seen the specially dangerous regions of the living anatomy searched, and while doing so, were the fingers which guided the instrument

the sole consideration? Surely never with me. Care and anxiety were in the surgeon's mind, that his knowledge of what he was about should be used to the highest and best of his capabilities for his patient's good, and with it the keen apprehension of some quick, undue movement which might lead to disaster.

This will, I thought, all be ended, and we shall now be able to operate upon quiet subjects, who will remember nothing but their ether sleep. It seemed too wonderful to be true; and yet, as I soon had the delight of seeing with my own eyes, it was an accomplished fact; for, although the first actual administration of ether which I witnessed was but a partial exhibition of its mercies, yet it was but a little while before abundant and repeated proofs became a part of my personal experience.

Hardly taking time for rest and refreshment after my voyage, I went to the Massachusetts General Hospital to observe for the first time the administration of ether, which, for a number of years, was, by many, particularly called, *sulphuric ether*.

The operation was for hemorrhoids. The subject was a man whose features and form indicated a prolonged period of suffering; he looked weak and decidedly below par every way. After being placed on the table, the attendant applied a sponge wet with the ether, down over the face and mouth of the patient, suddenly, and I doubt if there could have been more than two inhalations, perhaps only one, when the subject sprang from the table, and immediately there was a formidable display of activity and strength, which was speedily overcome by three or four men, who tried to master him and save him from hurting himself. The contest did not last more than two minutes. One man, who was herculean and always at hand in the operating-room, I think his name was Michael, found his match.

Pondering upon the scene I had witnessed, I was sceptical as to the efficacy of the new, hoped-for blessing; soon, however, I became witness of good results, for I was present at a number of surgical operations with the happiest effects, and it was natural that, among medical men, ether should be the grand topic of consideration. The thoughtful of the whole community gave evidence of delight upon the theme. Surgeons, especially, were enthusiastic; and it gives me a sense of joyousness in my declining years to be able to assert that not only was anesthesia deemed an advantageous aid to diagnosis and a great help to the mechanical part of their art, but that there was almost always an acknowledgment of its *supreme benefit to mankind*.

Under the acknowledged influence that the mind exerts over the body, I desire to say that, so far as circumstances may permit, with or without ether, the patient should have but little time for anticipation of the trial he is to undergo. I believe that, in many instances, the mental agony far surpasses that of the accomplishment; that the brain is surcharged; that the heart flutters; that the nervous system and all the vital forces are in an abnormal tumult; and that this condition remains long after the performance of the operation. It seems to me that surgeons in hospitals and in full practice are unapt to discriminate between those likely to be greatly disturbed in the contemplation of a surgical operation, and those who seem to have no great care about it. The mind of the surgeon is absorbed in the consideration and necessity of the

operation; due regard is not given to the mental welfare of the subject.

In my student life, and in the other years previous to the introduction of ether, much of the surgical work which it was my privilege to witness, and occasionally to conduct, was in private practice, and thus I have fallen into this homily; for my honored teachers were careful, as I vividly recall, in attending to the mental, as well as the physical, state of their patients, as being an important element to success.

Among the many great and important discoveries and inventions in the half-century which we celebrate to-day, and which have a bearing upon our profession, we should be remiss if we did not distinguish meritoriously our increased knowledge of the power of ether and of the manner of using it, as compared with what we knew in former years. We were presumptuous in its use, as though it carried no danger with itself. Now, however, all this is changed; a careful, competent investigation of the physical and mental condition of the subject is made and recorded, both before and after etherization. This is done in public institutions, and I doubt not in private practice.

The successful introduction of ether as an anesthetic became almost instantly universally known; and, for a number of years, doubts as to its safety and the probable danger in its use were discussed with greatest interest. This was natural, for we used to witness some scenes in the operating-rooms which would have greatly excited any audience but one of medical men: such as sudden, explosive exercise of muscular activity, catching hold of the sponge, screeching; so that restraint by assistants was required, and it was often several minutes before a persevering application of the sponge would bring about the desired condition.

In the surgical reports of to-day no mention is made of an anesthetic, unless some other than ether is given. The administering of ether has become a part of all surgical operations, and should be considered of importance in each. The present method of giving ether (that of holding a sponge saturated with it a few inches from the face, letting the patient get air and breathe gently, till it can be brought down over nose and mouth without a struggle) is even now done only by few really good administrators; many of them do not allow sufficient time, but seem to think the art of giving it well, is to give it in as short time as possible.

The approach and arrival of this present method have been slow. Many of us have witnessed scenes like that of my first visit to the hospital; but I am happy to say that this is past, and that the operating-theatre is as still and serene as it should be.

Who that sees an operation under its benign and quieting influence, with the knowledge of all the suffering spared, both to patient and witnesses, can call it other than a blessing?

AN EXPENSIVE TESTIMONIAL.—According to newspaper report, a veteran living in the interior of Massachusetts recently gave a testimonial to a patent-medicine manufacturer, stating that he had been entirely cured by his nostrum. It seems that he was receiving a pension for the ills of which the medicine cured him, and that when the authorities learned of his recovery, his pension was cut off. Is he likely to suffer relapse? and if he does will he get back his pension?

RECOLLECTIONS OF SURGERY BEFORE THE USE OF ANESTHETICS.¹

BY SAMUEL L. ABBOT, M.D.,

Member of the Board of Consultation of the Massachusetts General Hospital.

I REMEMBER very well the horrors of surgery before the discovery of anesthetics. It requires very little exercise of the imagination by those who happily never witnessed them to conceive what they must have been. And yet excellent surgery was done in those days under the most difficult and trying circumstances. I cannot recall, however, any serious accident caused by the resistance or struggles of the patient, nor any occasion when it became necessary to restrain him in any way except by the hands of the bystanders. Of course the most trying moment was that of the first incision. But there were always close at hand the house-surgeons and ward-tenders, ready to grasp the patient if necessary in such a way that he could not easily interrupt the work of the surgeon. The following steps of the operation were comparatively quiet, there being much less struggle and outcry on the part of the patient, who in many instances did his best to restrain himself. Operations were done as rapidly as possible. I think I have seen large amputations done in less than a minute, and not infrequently in less than a minute and a half.

The heroism of some of the patients was wonderful to witness. Thus I have seen a woman take her seat in the operating-chair in the arena of the operating-theatre, facing the amphitheatre filled with medical students, and quietly submit to having the whole of her left breast carefully removed without uttering a sound or moving a muscle. On another occasion I saw Dr. J. C. Warren apply the actual cautery to a poor fellow's back over the vertebrae at short intervals from the occiput down to the middle dorsal region, the cautery being held at each point until it had burnt in deeply as a moxa might do, without a sound of complaint or the slightest struggling movement by the patient. Such heroism, it need not be said, called out the most enthusiastic admiration of all present. I myself happened to be within three feet of him.

Two other scenes I remember brought to my mind the horrors of the Spanish Inquisition. The first of these was an operation upon a young man for the removal of a large cancerous growth on the end of his tongue. Dr. Warren, Sen., was the operator. The patient was seated in a high-backed chair, in the operating-theatre, and behind it stood Mr. now Dr. William J. Dale, a large, strong young man, who was then one of the house-surgeons. The operation was done by a short, quick stroke of the knife which removed the outer half of the tongue. Of course, the bleeding was quite free. The actual cautery, however, was in readiness, outside of the arena, in such a position that the patient could not see it, so that he did not know what was coming. Dr. Warren quickly stepped back to the portable furnace where the hot iron was, and as quickly brought it forward, holding it behind him so that the patient might not see it. At a look from Dr. Warren the house-surgeon quickly slipped both of his hands down over the patient's eyes and the cautery was instantly applied to the whole bleeding surface. The patient, being taken completely by surprise, made a convulsive start backwards, and

¹ Read at the Clinical Meeting of the Staff of the Massachusetts General Hospital, December 1, 1896.

notwithstanding the strong resistance on the part of Mr. Dale, was able to push the chair in which he was seated backwards some distance. He was followed up, however, by the surgeon until the cauterization was most complete, but in such a way that the lower lip of the patient was considerably singed. I remember well the immediate, dry remark of the surgeon, "Well, if you haven't burnt yourself it isn't your fault."

Another case of the terrible suffering of surgical patients before the discovery of anesthetics is pictured very vividly in my memory — that of a poor fellow who was suffering from an old unreduced dislocation of the right thigh upon the dorsum of the ilium. An attempt was made in the operating-theatre to reduce it by powerful mechanical traction, as all the usual methods of reduction had failed.

The patient was laid on a table lengthwise between the two opposite posts which bounded the curve at the bottom of the amphitheatre in the operating-room. A strong rope was fastened to one of the posts, which was carried in a loop over the patient's right groin and back again to the post where it was made fast, for counter-extension. Another rope with a large pulley-block upon it was fastened at the same level to the opposite post, for purposes of extension. Broad leather straps encircled the thigh of the patient, who was in line with the chord of the arc at the foot of the amphitheatre. The pulling, if I remember aright, was done by ward-tenders. The whole of the surgical staff were present, I believe, at the time. Extension was begun, and it was but a very few moments before it became very painful. Still the pulling continued, and now outcries of pain and expressions of agony came from the patient. Still the pulling kept on, as there was no sign of movement of the dislocated bone. In a few minutes the traction was suspended for a short time to give the patient a little rest, while the bone was manipulated by the surgeons to see if there were any indication of its starting. There was no sign of it, however, and the traction began again. Again an outburst of yells and screams, most horrible in my memory now, after the interval of so many years. And so it went on *for half an hour*, and without success. The bone was immovable and it seemed to me at the time almost, that the man's leg would be pulled off. I remember then thinking that the tortures of the Spanish Inquisition could not have been much worse. It was the most terrible exhibition of suffering I had ever witnessed. And to think that now such scenes are impossible!

I cannot help thinking that not infrequently familiarity with their work and the strong nervous tension under which they must have done it, may have temporarily blunted the sensibilities of surgeons to the suffering they caused. I well remember a case in point: A young member of the surgical staff was once confined to his house for some days by a deep abscess under the palmar fascia of his left hand, the inflammation extending to the end of the second finger. The pain attending it became so intense that he was obliged to summon Dr. J. Mason Warren in the middle of the night in the hope of getting relief. Dr. Warren at once made a deep incision through the palmar fascia, extending it to the end of the finger. After the patient's recovery, happening to meet him at the hospital, he told me of the terrible pain which the abscess caused him; he had never conceived of such

pain; and that of the incision was perfectly "infernal." He added that it was only a few days before that he did the same operation on an Irishman at the hospital, "who made such a row" about it "that I swore at him"; and then, after a pause he continued, "I never again shall swear at a patient I am operating on."

PERSONAL RECOLLECTIONS OF THE FIRST USE OF ANESTHETICS.¹

BY ISAAC F. GALLOUPE, M.D., LYNN.

My pupilage in medicine began in February, 1846, about eight months before the advent of anesthesia, with the late Dr. A. L. Peirson, of Salem, who was then the chief consulting and operating surgeon of Essex County, consequently I saw considerable surgery without the use of ether.

In chronic disease, requiring operative interference, the dread of the operation caused it to be put off as long as possible; and in many cases it was not done at all, the patient preferring death. Every means were used, by the friends and the surgeon, to induce the patient to be *willing* to have the operation done; having done this, to make him *anxious* to be relieved of his encumbrance. When this end had been attained, the patient would have courage to submit to the operation — at least, to have it begun. In some cases his courage would last until the operation was completed; but ever afterward he was a coward if the same kind of courage was needed again.

Before the operation (except in rare cases) large doses of opium — say a teaspoonful of laudanum — were given, and brandy *pro re nata*. It was necessary to have two or three strong men at hand to ensure the quiet required by the surgeon. Tying the patient I have never seen. In 1872, while visiting the Edinburgh Infirmary, Mr. Lister showed me some large iron rings, fastened to the floor, formerly used for binding the patient down — now kept as mementos.

In the case of recent accidents the surgeon went at his work without inquiring of the patient as to his wishes in the case.

Shortly before the first trial of ether, at the Massachusetts General Hospital, Dr. Horace Wells, of Connecticut, had the opportunity to exhibit the use of nitrous oxide as an anesthetic. He had implicit confidence in the success of his experiment, and was a greatly surprised man when he saw its failure, other things (mesmerism, etc.) having been tried with non-success.

Dr. Morton's claim was that he had discovered a compound, the inhalation of which would cause insensibility to pain. He wished it tested by the surgeons at the hospitals; but they would not consent unless he would first reveal to them its composition. This he was reluctant to do, but finally consented. The faculty and students looked with derision upon Dr. Morton's claim. In this state of mind we assembled, in the operating-room of the hospital on the 16th of October, 1846, to witness the first administration of ether in the Massachusetts General Hospital.

As I recollect, there were present Drs. J. C. and J. Mason Warren, Drs. Townsend, Hayward, Parkman, H. J. Bigelow, and A. L. Peirson, of Salem. Dr. Morton was to be there at 10 o'clock; the doctors,

¹ Read before the Clinical Meeting of the Staff of the Massachusetts General Hospital, December 1, 1896.

ward-tenders, students and the patient were ready—but not Dr. Morton. Dr. Warren, who was to operate, waited a half-hour; he then remarked, sarcastically, "Dr. Morton has not come, perhaps he has another engagement." Then followed sneering remarks by the students, and sneering looks by the surgeons, for no one had faith in the experiment, and the students enjoyed the fun of the anticipated failure, myself with the rest.

As Dr. Warren was about to begin the operation, Dr. Morton came in, out of breath, and red in the face from hurry. He immediately commenced to give the ether from the glass inhaler then used. In three or four minutes he turned to Dr. Warren, and said, "Your patient is ready"; whereupon the operation was done without a sign of pain that I could see. Dr. Warren then stood facing the class, and said, "Gentlemen, *this is no humbug.*" We were *thunderstruck*. Dr. Warren was a tall, straight man, dignified and rather solemn in manner, with supreme self-control, laconic in speech, using the fewest words possible and never repeating them (resembling the Duke of Wellington); yet there were tears glistening on his face when he uttered those words.

Now for the explanation of Dr. Morton's tardiness. On the previous day (October 15th) Dr. Gould, a friend of Dr. Morton, suggested that valves be put in the inhaler to aid the elimination of the expired air. At midnight he (Morton) had thought out the way to do it; he then went to the house of Mr. Drake, philosophical-instrument maker, rang him out of bed, hurried him to his shop, and induced him to make the required alterations. This took him well into the next forenoon; hence Dr. Morton's delay.

In order to fully satisfy the minds of all that the Lethæon was a *complete* destroyer of pain, it was proposed to make the severest test, namely, that of the actual cautery. It was applied, accordingly, to the back of a man suffering from caries of the spine. The iron, heated to a white heat, was passed up one side of the spine and twice upon the other side, a distance of two feet, and then zigzag between the spinous processes for the same distance. The room was filled with the odor of burning flesh and smoke, but the man did not wince. Dr. Warren said that this was the severest test possible, and proved the complete success of ether as a destroyer of pain.

A young woman named Alice Mohan was brought into a surgical ward suffering from disease of the knee, for which amputation had been advised but declined from dread of the operation, she preferring death. Dr. Hayward told her that he could give her something that would put her to sleep and make the operation painless, when she readily consented to have it done. This was the first amputation under ether. It was done by Dr. Hayward, November 7, 1846.

Dr. Warren substituted chloric ether for sulphuric and seemed to prefer it.

The first recorded case of extraction of teeth under ether was on the 30th of September, 1846, by Dr. Morton. He began his experiments by pouring the ether on cloths; that not being satisfactory, an inhaler of some kind was thought necessary. Many different kinds were tried, but none were without faults. In the early part of April, 1847, Dr. Morton abandoned them all for the cone-shaped sponge. No important knowledge has been gained connected with the administration of ether since that date.

It appears that ether was used, by inhalation, for asthma and phthisis as far back as 1818; and, singularly enough, the greatest care was used not to carry it to unconsciousness for fear of fatal results, several cases of death having been recorded from that cause.

PERSONAL RECOLLECTIONS OF THE INTRODUCTION OF ANESTHESIA.¹

BY C. V. BEMIS, M.D., MEDFORD, MASS.

IN replying to the request of your committee that as a witness of the first operation under ether, at the Massachusetts General Hospital, I would relate some of the incidents of that occasion, the first thought is that little remains to be said; that the events of that day have long ago become historical.

The picture of the theatre at that time is distinctly before me.

In the old days, the private pupils of the late Dr. John C. Warren, of whom I was one, were accustomed to assist in his operations at the hospital; and after graduation, I continued to make very frequent visits there, especially on the regular days for operations. On one of these days, the famous first operation under ether was performed.

I think nearly all of the Surgical Staff were present. I remember that Dr. Peirson, of the Board of Consultation, was there. The theatre was quite well filled with students and the younger professional men; among whom I remember Dr. George H. Gay, Dr. H. G. Clark, Dr. W. W. Wellington, Dr. Daniel D. Slade.

All waited impatiently for the arrival of Dr. Morton, who had been detained, and was late in keeping his appointment with Dr. Warren.

Immediately on Dr. Morton's hurried arrival, he began the administration of ether to the patient, already on the operating-table, through a tube connected with a glass globe which contained it; and the operation was completed quietly and without special incident.

AN INCIDENT IN THE EARLY HISTORY OF THE INTRODUCTION OF SULPHURIC ETHER AS AN ANESTHETIC.¹

BY W. G. WHEELER, M.D., CHELSEA, MASS.

IN the early part of the year 1846, a New England travelling man from Boston, on his way to the West, arrived at Little Falls, N. Y., then a village, now a city in the valley of the Mohawk. He announced himself in a circular as the agent for and interested in a wonderful discovery which he wished to exhibit; also that he would sell to dentists, physicians and surgeons the right to use the new and powerful agent which would render the extraction of teeth and all surgical operations painless. He also, by written notes to the physicians and a few of the leading citizens of the town, invited them to visit his rooms the next afternoon, to witness the effect of this oblivious drug and to see the extraction of a tooth, without pain, while the patient was under its influence.

This was a great announcement; and it required considerable faith on our part to accept the Boston

¹ Read at the Clinical Meeting of the Staff of the Massachusetts General Hospital, December 1, 1896.

man's notion and all that he promised. However, at the specified hour, some half-a-dozen physicians and one dentist called upon him. In his room we found an ordinary operating-chair. On a small table near by was an old-fashioned "wine decanter" half-filled with a bright-red liquid; two glass tubes (one longer than the other) passed down through the large cork, and attached to the affair was some small rubber tubing, three feet in length, with a felt cone on the end, moulded so as to cover the mouth and the nose.

Soon an elderly man, dressed like a farmer, entered; with fear and agitation he seated himself in the operating-chair, and the mouth-piece was readily adjusted. He was told to breathe in, long and deep down. During the first few inhalations he was excited, and resisted; but soon his respirations became slow and stertorous, the muscular system relaxed, the lower jaw dropped and the eyelids closed. The dentist then applied his forceps to one of the patient's molars, and out it came. In fifteen to twenty minutes, consciousness returned, and the victim's face was the expression of wonderment and surprise, as he beheld the offending member within the grip of the dentist's forceps. The patient was questioned as to his sensations, of which he could only say that he knew nothing, was glad it was out, and that he felt no pain.

The physicians asked the agent a few questions as to the *modus operandi* of this Letheon, as to how long the anesthetic effects lasted, and if it had to be repeated. It was then he seemed quite oblivious and could tell us little or nothing, but said it was safe, and that no accident had happened as far as he knew. But we found that he could tell us the exact price, or the royalty per month to be paid for the right to use the article in our surgical operations. And let me say that none of us present ventured to purchase a royalty. But we left his room somewhat surprised, and somewhat doubtful as to what we had seen of the "Boston notion," or the "newly discovered Letheon."

The question of consciousness, or rather the amount of pain that the patient was sensible of? This was the unknown quantity in the problem before us. Some of the doctors seemed sceptical, and said that there were manifestations of pain; one concluded that there had been collusion between the operator and his patient. And then, to add to our perplexity, the name signified nothing as to its chemical elements; the bright color was suggestive of danger ahead. We all readily smelt the pungent fumes of sulphuric ether, and were quite certain that this was an important constituent of the oblivious compound.

Such was the humble advent of "surgical anesthesia," this mighty boon of the nineteenth century, on its mission of mercy to relieve suffering humanity.

The discovery of ether (or rather the anesthetic property of sulphuric ether) this was the beneficent gift of painless surgery, vouchsafed to our profession for all time.

The city of Boston was its home and its birth-place. The Massachusetts General Hospital was its public sponsor at its baptism and will be the fitting custodian of its memory to the "Coming Ages."

LISTER SUCCEEDS ERICHSSEN.—Sir Joseph Lister has accepted the appointment of consulting surgeon to the City of London Hospital for Diseases of the Chest at Victoria Park, succeeding the late Sir John Erichsen, F.R.S., in this office.

THE SURGICAL RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL BEFORE 1846.¹

BY H. H. A. BEACH, M.D., BOSTON.

A GLANCE at the earliest events connected with the development of the hospital, reveals the interest of Dr. John C. Warren its first surgeon, and of his father, Dr. John Warren (brother of General Warren), in its organization. In a letter sent home from London, July 9, 1800, he writes: "I have heard nothing of the hospital which was to be established in Boston. Does it progress? And have you, sir, a prospect of getting appointed to it?"²

We are told by the historian of the hospital,³ that a circular letter to the citizens of Boston, signed by Drs. James Jackson and John C. Warren, "may be regarded as the corner-stone of our institution." That strong appeal for financial aid, met with a liberal recognition; and as a result the charter was obtained in 1811. It entitled the holders to real and personal estate to the yearly value of \$30,000. A board of trustees was elected in 1813.

On April 6, 1817, a consulting staff was chosen, and the positions of attending physician and surgeon were filled for the first time by the appointment of Dr. James Jackson and Dr. John C. Warren.

Land for the hospital was purchased October 6, 1817, and the Bulfinch plan was adopted by the trustees, February 1, 1818.

The corner-stone was laid on July 4th, under which was placed a tablet engraved with the following inscription:

"The corner-stone of this edifice, designed as a general hospital, founded by the munificence of the Commonwealth of Massachusetts, was laid at the request of the Trustees of the Massachusetts General Hospital by the Grand Lodge of Massachusetts, Francis J. Oliver, Grand Master; His Excellency John Brooks, Governor; His Honor William Phillips, Lieutenant-Governor, President of said corporation, and a most munificent donor, the municipal and military officers of Boston, assisting at the ceremonies.

"The fourth day of July. MDCCCXVIII, and of the Independence of the United States XLIII. Anno Luce 5818."

"The accommodations of the hospital were intended to give to a few, in a superior style, everything which their comfort or well-doing demanded. The poor patient was sure of receiving all the care and attention and of having everything which would promote his cure, equally with the rich. The man of property might find all the accommodations of his own house, in addition to those remedial measures, such as baths, apparatus, and nurses of superior order, which he could not obtain at home. There was nothing left undone which care, medical skill, cleanliness, pure air, perfect ventilation and strict discipline could accomplish, nothing was wanting that could contribute to the ultimate success of an operation or the cure of a disease."⁴

"The origin, arrangement and in a great degree, control, of this institution in its earlier years belonged to Drs. Jackson and Warren. The trustees acted by their advice as the persons most interested in its welfare and best qualified by their profession to superintend it."

The first patient was admitted to the surgical wards for treatment on September 20, 1821, beginning the long and eminent services of Dr. Warren to the hospital, which only ended with his retirement in 1852.

¹ Read at the Clinical Meeting of the Staff of the Massachusetts General Hospital, December 1, 1896.

² Life of John C. Warren, p. 206.

³ Bowditch.

⁴ Edward Warren: Life of John C. Warren.

As the advantages of hospital treatment became known, the attendance increased until the admissions which, in 1846, had reached the number of 9,980, have to the present time become 101,162. During the past thirty years the increase in surgical operations, especially those of large scope, has risen, in the ten years ending at 1877, to 7,443; at 1887, to 7,880; and to October 1, 1896, to 12,425; a total of 21,748 in thirty years lacking six months.

In addition, the number of out-patients treated since the establishment of that department in 1864, has reached the number of 120,000; and the minor operations performed in that department and in the accident-room average 3,216 in a year (not included in the estimate of operations just given).

An eye-witness of many a bloody struggle between operators, patients and assistants in and out of hospitals, has characterized the fearful scenes that commonly occurred before the days of anesthesia, as fights exhausting alike to all concerned, but to which suffering humanity willingly turned for the relief of deformity, pain and the saving of life.

The grim associations of the old operating-theatre have been dispersed by what Sir Joseph Lister calls "the priceless blessing to mankind from America."

Present generations have appeared with the birth-right of anesthesia, sunshine and air. Few living witnesses can paint for them a perspective of surgery without anesthesia, describe the wonder and astonishment it produced, or its power in developing the science and art of surgery.

A short review of the earlier records may supply facts that will revive the atmosphere of the period and convey some idea of the relief that ether brought, alike to patient and surgeon — whose great and stern duty it was to be self-forgotten, strong and faithful while inflicting the worst tortures upon suffering men, women and children.

The first surgical record was a folio volume of 247 pages. It was sufficiently large to contain the histories of surgical patients admitted in the years 1821, 1822 and 1823. At the present time, six volumes of very nearly the same size are used in making the records of eight or nine months. The operations to be described, selected with care after an examination of every record of surgical cases admitted between the establishment of the hospital and the year 1846, were performed with few exceptions in this theatre.

The first history recorded is that of a seaman who had been afflicted with hemorrhoids for eleven years. His many voyages to India, China, the West Indies and America in that time were complicated with much pain, tenesmus, bleeding, debility, difficulty in walking, and at times with complete disability. Purgative medicines were continually necessary for his comfort.

An examination was made in order to ascertain the cause of his complaint. A stricture was found to exist in the rectum two or three inches from the verge of the anus, which with great difficulty would admit the tip of the forefinger. Several tubercles were found around the anus. Three of them were removed, first passing a curved needle with a large ligature through them and drawing them out in order to extirpate them at their bases with a knife. Very little blood was lost. Light dressing. Five days after, hemorrhage of a pint of blood, checked by cold applications and injections of a solution of sulphate of copper.

Bougies were passed to dilate the stricture, as the wounds gradually healed.

Patient discharged cured.

The second patient was a young man who had suffered intolerably for a year with symptoms of stone in the bladder. They had followed the introduction of a bean into the bladder with the intention of dilating an obstructed urethra. The obstruction had followed a slight injury of the urethra received from a fall. The record is illustrative of the care taken in preparing for an operation and exemplifies the surgical therapeutics of the times.

On the 8th of October a convention of the consulting staff (seven in number) was held, but the stone was not felt and the operation was postponed. In the following week, after an injection of the bowels, the sound was passed and heard to strike distinctly upon a stone. The operation was decided upon for October 18th, at 12 o'clock.

MEMORANDUM OF ARTICLES, ETC., TO BE IN READINESS FOR THE OPERATION.

A heavy table; table for dressings; pillows, blankets and sheets; binders, sponges, lint compresses and bandages, towels, oil, ice, syringe, ligatures, warm and cold water, wine and water, warm barley-water, basins, blood-catcher, coat.

INSTRUMENTS.

Staff-knife, pointed knife, Cooper's knife, probe, pointed bistoury, gorget, forceps, scoop, sound, needles, tenaculum, canula, needles and forceps.

PREPARATION.

The patient, well-purged the day before, early in the morning of the operation should have a good injection. After this has operated, a string must be tied on the penis four hours before the operation to retain the urine. The hair must have been well-shaved. Laudanum injected, 120 drops to the cup.

ARRANGEMENT OF PATIENT.

Assistant adjusts head, secures the feet. Two at shoulders. Staff introduced. Assistant holds it straight; then to the right; then carries the handle down; retains it until ordered, touching the stone.

OPERATION.

Tighten skin, take knife. Incision of four inches deep above. Cut transversus, avoid rectum, feel bulb, touch staff, lay bare staff. Introduce probe-knife flat, and push into bladder. Observe urine. Cut gently towards ischium, following knife with the forefinger into the bladder. Enlarge if necessary. Scoop or forceps introduced. Staff withdrawn, first touch stone. Carry forceps along staff to stone, finger in the wound, finger in the rectum. Search stone, low down. Withdraw downward. Dressing, lint in wound. Patient untied.

The stone was small, and broke during its extraction; the remainder was removed with difficulty with a scoop, and the bladder syringed out with warm water. The latter gave great pain, and did not appear to remove any fragments of stone. The patient expressed great pain in every part of the operation as he had done in sounding. One hundred and eighty drops of laudanum were given to relieve pain at intervals after the operation.

October 19th (the following day). Complaints of severe pain in the bowels and hypogastric region. Slight flush on the cheeks. Sixteen ounces of blood taken from the arm. Tartrate of soda and potash, half an ounce every three hours until a discharge from the bowels occurs. At 5 P. M., a small discharge. No flush on the face. Skin warm. No opiate.

Hyd. submur.	gr. xii
Pulv. opi	gr. iiii
Ft pil, no. xii. Take one every three hours.						

October 20th. Much better. No flush on the face. Slept well. Had three discharges from bowels.

Tartrate of soda and potash	.	.	.	3 ss at once.
Pills as before				

Evening: Skin warm. An injection of one pint of gruel with a tablespoonful of salt, wine-glass of molasses and sweet-oil. Suffered from great pain after the injection. In fifteen minutes one-half came away; pain continued but not so violent.

October 21st. Had three discharges during the night. Evening:

Tartrate of soda and potash 3 ss

October 22d. A little sallow in the face. Pulse 77, quick, but not hard. Suppuration going on well in the wound. Evening, pulse 80, a little hard.

Tartrate of soda and potash 3 ss
Pills as before.

October 23d. No evacuation from the bowels.

Tartrate of soda and potash 3 ss
Immediately.

At 1 P. M., as before, gums sore. Omit pills.

Tartrate of soda and potash 3 ss

At 7 P. M., considerable pain and movement of the bowels. One small discharge. Fomentations applied.

Tartrate of soda and potash 3 ss
Immediately.

At 8 P. M., medicine not operated. Complains of wind in bowels, with pain. Pulse 90, a little hard and more full.

Tartrate of soda and potash 3 ss

Midnight: Great pain in the bowels; very restless; pain in the wound. Pulse 100. Take twelve ounces of blood from the arm. Fulness of pulse subsides. Pain continues. Forty drops of laudanum.

October 24th. Medicine operated four times toward morning. Considerable pain all night. Slept half an hour. Pulse 92. No pill this A. M. Take one tonight. At 5 P. M., pulse as before. Tongue moist. Pain and soreness in the bowels.

Vini antimonii 3 i
Spt. nit. eth. 3 ss M.
Camph. tr. opii
Thirty drops every two hours until asleep.

Wounds look better. Hot fomentations, with tansy and wormwood.

October 25th. Took drops twice. Bowels easier. Sleeps considerably. Pulse 120, more hard. White fur on tongue; edges well-defined. Mercurial fetor in the breath. Wound looks well; edges not much swollen; good granulations shooting up. Urine passes freely from wound.

Olei ricini 3 ss
Essent. menth. pip. gtt. x
Every three hours until it operates.

October 26th. Mouth and throat very sore. Oil operated twice. Pulse 120, hard. Tongue as before. Evening: More pain in bowels. Hot fomentations. Abdomen rather tense. Skin hot and sweating. Cold chills. Pulse as before. Brown fur on tongue. Very thirsty. Blister to abdomen. Ol. ricini half an ounce.

October 27th. Blister on four and one-half hours. Five discharges in the night. Wound inclined to heal.

October 28th. Countenance better. No pain in bowels. Pulse 120, less full. Tongue moist. Mouth and throat more inflamed.

Olei ricini 3 ss

October 29th. Slept well. No pain but in mouth and fauces. Pulse 108, not hard. No discharge from bowels.

Pulv. rhel 3 i
Aq. bul. 3 ii
Aq. cinna. 3 i M.

October 30th. Pulse 92. No pain in bowels.

October 31st. Discharge of urine by urethra. No movement of bowels.

Olei ricini 3 ss

November 1st. Pulse 112. Wound diminishing. Suppuration healthy. Medicine operated twice.

November 2d. Good night. No movement of bowels.

Olei ricini 3 ss

November 3d. Two operations from oil. Face and throat still painful. Little salivation.

November 4th. One discharge from bowels. Pulse 90. Pains as yesterday.

November 5th. Pulse 88. Considerable wind in the bowels last night.

Olei ricini 3 ii
Comp. tr. senna 3 i
Essent. menth. pip. gtt. x M.

November 6th. Face sore without pain. Pulse 82. Good night. Medicine operated twice yesterday.

November 7th. Face better. Pulse 86. Appetite improving.

November 8th. No discharge from bowels. Symptoms same.

November 9th. Disposition to diarrhea. Pulse 85.

November 10th. Pulse 76. One stool yesterday and one in the night. Urine passes freely through the urethra.

During the following six weeks his progress had the usual interruptions of no movement, cathartics movements, diarrhea, the wound in the meantime becoming firmly healed. He left the hospital well.

The next case of interest was one of popliteal aneurism. The preparation for operation consisted of a bath, clearing the bowels for a few days, opium to relieve pain, and eight ounces of blood from the left arm three days before the time appointed. Two hours before the operation the patient (a woman) took six grains of opium; and as the muscles were relaxed so that their course could not be determined, the place for making the incision was settled by carrying a line from the point of the inguinal artery in the groin down to the inner edge of the patella. Another line was carried from the anterior superior spinous process of ilium to the back part of the internal condyle. One inch and a half below the point of meeting of these two lines, the incision began, and was extended upward nearly three inches toward the inguinal artery (left side). The usual dissection for tying the femoral artery was made and afterward closed. A flannel bandage was applied, and forty drops of laudanum given. The wound healed by first intention above and below the ligature. She left the hospital cured of her aneurism.

The operation for fistula ani was commonly done with giving opium or spirit.

C. B., an officer of the frigate *Constitution*, entered the hospital October 25, 1821, with urethritis; and he left it, cured, on November 9th.

C. L., male, adult, was admitted December 7, 1821, with dislocation of the left femur. The accident occurred in September, when he was thrown from a horse, and while lying on his back received the body of the horse across his thigh. His physician recognized the dislocation. The leg remained fixed in an oblique position with respect to his body; he had not the least command of it, and was in considerable pain.

The physician immediately undertook the reduction, and after about ten minutes of considerable force told him that it was reduced. The patient experienced no alleviation of his pain, neither had he the power of motion in the limb; it still remained in the same position. Not satisfied, he sent for another physician who arrived in four hours, and he declared the dislocation to be still unreduced. He immediately bled the patient about twelve ounces, and then undertook the reduction. After trying a short time, he told the patient that it was then reduced, and the patient agreed that it was. The leg could be brought nearer the other; but still there was a tendency to the oblique position — a constant inclination outward. A bandage was put about the knees to keep the thighs together. This physician then left him. He felt some relieved, and was able to sleep some that night. The next day he was again bled about a pint, and took some purgative medicine. He was then seen by the physician who first examined him, and told that the bone was broken in the neck. The patient lay on his back for fourteen days after, and then began to walk with crutches. The second physician examined him again after eight days, and told him that he was doing well. He came again in about ten days and said the same, although the patient had then no command over his leg.

About two months from the time of the accident, on visiting him his physician ascertained that the affected leg was longer than the sound one; he then told him that the thigh was not reduced. No efforts had since been made for its reduction. His health otherwise was good. Upon examination it was ascertained that the femur was dislocated and the direction as far as could be ascertained was downwards and backwards, in consequence of which the affected limb was longer than the sound one. The head of the bone was distinctly felt through the inferior border of the gluteus muscle. Considering the time that had elapsed since the accident and the difficulty of reduction of dislocations in this direction even when recent, it was thought advisable not to undertake an operation; but the patient being very anxious to have a trial made, and still desiring it after it was stated to him that there was hardly a possibility of succeeding, it was thought justifiable to attempt the reduction of the bone. On the day of the admission of the patient he was ordered to take

Magnesia sulph.	:	:	:	:	:	:	5i
Fol. sennæ	:	:	:	:	:	:	3 ss

and to live light; next day a warm bath was ordered. At two o'clock he began taking tart. antim., gr. i. every ten minutes, until the operation. He took five grains, when vomiting was induced. At three o'clock was bled to sixteen ounces, but no faintness was produced. The operation was immediately proceeded with, and after continuing it about an hour the case was abandoned as hopeless.

December 10th. Discharged by request.

This case became celebrated through the suit of the patient against the two physicians who first attended him, for damages, contrary to the advice of Dr. Warren. In the testimony given Dr. Warren maintained the fact of dislocation, and in that view of the case he was supported by the consulting surgeons of the hospital. The juries disagreed, and the patient lived with a shortened and partly-flexed leg until thirty-seven years afterward, when at his death, Dr. J. Mason Warren was notified by his friends that an examina-

tion was desired. At Dr. Warren's request, Dr. H. K. Oliver went to Ellsworth, Me., and removed the pelvis with the upper part of the femur of each side, and brought the mass to Boston for a careful dissection of the parts. In the course of the dissection Dr. Warren's diagnosis of dislocation was verified; and after the bones had been macerated they were mounted and deposited in the museum of the Harvard Medical School. An interesting account of the case and the dissection of the specimen, with a plate illustrating the latter, may be found on page 372 of "Surgical Observations, with Cases," by J. Mason Warren, M.D.

In a case of gangrene of the foot and leg following a compound fracture of both bones of the leg, the following preparations were made before amputating the limb: "The patient was gently purged with tincture of rhubarb the day before, supported by some wine and water and good broth. Laudanum, if necessary. Forty minutes before operation a strong dose of laudanum was given before being carried to the operating-theatre at ten o'clock with dressings on except pillows and cradle. Laid on table, with his hands raised and held by two persons; knees six inches below the edge of table; each leg supported by an assistant."

A woman of forty-nine entered, with a tumor of the breast, April 24th. All things being ready, operation commenced by making a semilunar incision from the axilla to the sternum, and a similar one from the same point above the nipple. The tumor was dissected out with about one-third of the breast, beginning at the sternal part and advancing toward the axilla. Several glands there were enlarged and indurated. They were taken out (a foreshadowing of the modern operation).

Compound fracture of both patellæ. The injury was caused by the kick of a horse. A loose portion of the right bone removed. Both knees became much swollen. Had been bled freely. Alkaline cathartic. Calomel and opium every three hours. Leeches to the joints. Gruel and tea. No solid food. Apply a wash to the joints of plumbi acet. Profuse suppuration of the right joint followed. Discharged well, in two and one-half months, with good union.

In the description of the excision of a considerable tumor of the lower jaw from a man about thirty-four years old, the record states that the operation was performed and the wound dressed in forty-five minutes — rather tedious to the patient from the proximity of the tumor to an important artery and other parts of consequence. It was borne, on the whole, with a good deal of fortitude. During the operation the patient occasionally took wine and water to drink.

For the removal of piles in another case, a spring-hook was now passed through the largest tumor and drawn downwards, which exposed its full extent. The tumor was then removed by a single excision with a scalpel, and with the loss of a small quantity of blood. The others were treated in the same way. The patient was allowed a little wine and water for faintness.

During an operation for fistula in ano upon a young man, the integuments and a portion of the cellular substance was divided for the space of half an inch towards the anus and through the whole depth of the ulcer. No obstacle now presenting, the patient being secured upon the bed by five assistants, one at each lower and upper extremity and one at the head and one on each side to assist in extending the parts, an attempt was made to thrust the bistoury through the

coats of the rectum; but such was the resistance and the danger of breaking the instruments that a further attempt was useless. A careful dissection was, however, made. The patient during the operation complained of great pain, but bore it well.

The large variety of operations undertaken at the hospital included a number for cataract, from one of which the notes are as follows:

A woman of seventy-five years entered the hospital November 4th. From then until the 27th, when the operation was performed, she was purged and dieted. The eyelids, which were somewhat irritated, were treated, and the pupils kept well dilated by the external application of a preparation of belladonna. The operation was done by breaking up the cataracts with a needle and pushing the fragments into the anterior chamber. This was accomplished without much pain to the patient. Later, as the right eye did not clear up satisfactorily, the operation was repeated, and the cataract, which was very firm, depressed into the vitreous. A successful result occurred.

In another case, during the removal of some carious bone from a rib, the patient was given eighty drops of laudanum forty-five minutes previously. Being fixed upon the table and secured, by three assistants, the bone was exposed and the carious portion removed by chisel and forceps. The operation was borne with a good deal of fortitude.

Large fatty tumor of abdomen. The patient, a young woman, was given forty drops of laudanum half an hour before operating. The incision required was twelve inches, and she was held by three assistants. For most of the time during the operation was very uneasy and complained of great thirst and exhibited some signs of delirium. After being removed to her bed she became more tranquil.

In a case of aneurism, during the dissection necessary to expose the iliac artery (the patient having previously taken an opiate), when the time arrived to open the sheath of the vessel "the patient was directed to keep himself perfectly still at the moment when a division of the sheath was made over the artery in order to lay bare the coats of the artery and to separate it so as to pass the aneurismal needle completely around it and under its sheath, after which, the ligature was tied with a double knot. The patient endured the operation with considerable firmness."

An early employment of surface thermometry occurs in the subsequent treatment of the case when the following entry is made:

"February 20, 1823. Temperature of the limbs by the thermometer as follows; right limb, just below groin inside, 98°, at sole of foot, 96°; left limb (sound), inside of thigh, 97°, at sole of foot, 94°."

The ligature came away on the nineteenth day, there having been abundant suppuration.

March 18th. Limbs both alike as to strength and temperature. Discharged cured.

Nerve section. The case was one of severe neuralgia of the fifth pair. After the facial nerve had been severed at the point where it emerges from the skull, there was so much suffering that another operation was undertaken.

February 26, 1823. The patient having taken three grains of opium was seated in a convenient chair and an incision made beginning just below the zygomatic process of the os temporis and over the body of the inferior maxillary bone on the right side.

The first incision through the integuments and subjacent cellular membrane exposed the anterior portion of the parotid gland and the fibres of the masseter muscle. The dissection was then continued through the glands dividing the duct and thence carried through the muscle to the bone without dividing any considerable artery except one which was secured by a ligature. The great facial artery was exposed in the upper part of the wound. The bone being laid bare of the muscles which covered the spot opposite to the foramen for the passage of the inferior maxillary nerve into the bone, the raspatory was applied, and the periosteum removed. The trephine was next applied, and the bone perforated just opposite to the foramen, as was shown by a furrow or notch in that portion of the bone which was removed, bringing with it a portion of the nerve with one of its branches. The remaining part of the nerve was then drawn out by the forceps and cut off at the foramen, and the other end divided, making the piece removed about half an inch long and something more. The divided ends of the parotid duct were brought together by a suture. The patient walked to his room pretty well satisfied that the desired relief was obtained. Discharged cured.

Necrosis of the tibia. The necessity of a protracted operation without anesthesia is well illustrated by the next case described.

The patient (a man) was placed upon the table and held by assistants. Surgeon first made an examination with probe, learned the extent of the dead bone and the firmness and strength of the living bone. He then commenced the operation by making a longitudinal incision through the integuments of about four inches, which he afterwards crossed with another of two inches, and then carefully dissected up the integuments and exposed the bone, which proved to be thick and firm. The sequestrum was completely encased, excepting at the orifices where the matter escaped. To effect the removal of this, the raspatory was applied to the external surface of the bone. The trephine was then used and the chisel and gouge until a portion of the living bone was taken out and a part of the dead bone laid bare. A probe was again passed in, a further examination made, and the cavity ascertained to be well filled with the old bone. The operator proceeded to the removal of more of the new-formed bone using one of Hey's saws, gouge, chisel, etc., as particular circumstances required. At the same time incisions through the integuments were carried further, others made cross-wise and the flaps dissected up.

Though a good part of the sequestrum was now exhibited, it was found necessary to divide it before it could be taken out. It was accordingly done with Hey's saw, and two portions of the bone extracted without any difficulty. In consequence of the ragged edges of the dead bone being strongly interlocked in those of the new-formed bone, successive portions of the sound bone were again and again removed by the same instruments until the whole sequestrum was extracted and the operation completed. The dead portion of the bone was found to extend nearly the whole length of the tibia, and the newly-formed bone sufficient for the strength of the limb.

The patient was conveyed to his bed much exhausted. During the operation his strength was supported with wine. The operation continued about two hours, and was borne by the patient with great fortitude.

Some of the difficulties in operating for cataract are shown by the next case, which was that of a child.

April 26th. The usual preparation being made, seats adjusted and the child held by a female sitting in a chair, the speculum was applied, and the surgeon passed the needle into the eye, puncturing and dividing the cataract. During the operation the child made much resistance, with cries. The upper eyelid was inverted, which together with the tears almost entirely obstructed the site of the operation. Occasionally the opaque spot appeared to view, and was very well lacerated. Small compresses of lint were applied with bandages around the head and in a short time, the child was perfectly quiet.

The following quotation is made from the description of another case of double cataract: "Depressing the cataract was somewhat embarrassed from the circumstance that the patient, a woman of sixty-five, during the operation sunk a little forward in the chair, which of course depressed the head and altered its position in such a way that the operator was obliged to raise his head, which gave only an imperfect support to his elbow and proved rather inconvenient. The operation for depression was performed on the right eye with the left hand of the operator."

In another double cataract operation the "patient suffered considerably during the operation upon the left eye, very little in that of the right."

Dr. Warren's biographer tells us that not an eye was lost by cataract operations.

Shoulder-joint dislocation. The patient was a man sixty-two years old, and the dislocation had existed eight weeks. It was sub-coracoid. *Magnesiae sulph. sol.*, *qs.* Warm bath.

"To-morrow at 10 let him be bled in the erect position so as to faint. At 11 take 1 grain of tartarized antimony every fifteen minutes until nauseated. Operation at 12.

"Patient placed upon a stool. Pulleys and straps applied. Padded belt under the axilla, and secured to opposite wall. Extension then made by pulleys attached to a strap buckled at the arm, the latter at right angle with the body. The muscles became relaxed very considerably, and an effort was made, by bringing the arm forward and upward to replace the bone, but ineffectually.

"Extension was next made nearly in front of the patient, downward, and a powerful, but gradual, extension made, but without reducing the bone. The patient suffered much pain from the severity of the process, but did not refuse a further trial. Accordingly he was directed to lie on his back. The bite was passed under the axilla and secured firmly to the floor by the cord used for counter-extension, then extension was made on the arm nearly in the natural direction of the limb, the body of the patient being in line with that of the extending force. This position was very favorable for reduction, and the bone had apparently got into its place, for a hollow on the outside of the shoulder was filled up, and the head of the bone, by the pressure of the belt in the axilla, was carried toward the socket. At this time the extension was relaxed, the arm brought forward and upward over the body, but without effecting the desired object. Is thirsty. Wishes for brandy and is given two glasses. Eloped."

Neuralgia of the intra-orbital branch of the fifth pair, left side. The patient was a woman of fifty-one

years, who had suffered for eighteen years almost constant pain. For six months anodynes had been occasionally taken at night with advantage. Patient given half an ounce of sulphate of magnesia. "On the following day, the back and head supported by assistants, an incision made over the nerve from the orbit downward" the seat of the nerve was determined by passing a probe into the wound. Then with the forceps a portion of the nerve was removed. As the pain persisted without much abatement and extended to the lower jaw, three teeth were extracted; and she was discharged cured in a few days.

An amputation by transfixion of the thigh, for white swelling of the knee-joint, is described as having been done in sixty-five seconds. The patient died in three days.

A carpenter, while engaged in erecting an arch in honor of Marquis Lafayette, on August 23, 1824, fell from the ladder on which he was working to the ground. He jumped, and fractured his left femur. The limb was placed in a fracture box, and an eighteen-tailed bandage applied. He was discharged cured.

From the record of a patient who submitted to the removal of a large tumor of the breast with extensive dissection: "She sustained the operation with great calmness — was much exhausted and faint."

Necrosed bone from the tibia. "Let the patient take twenty drops of tincture of opium one hour before operation. An incision from three inches below the knee, carried down over the anterior edge of the tibia to the ankle, also a cross incision at each end of the longitudinal one. This portion dissected up, leaving bare the tibia. The bone at the lower part was sawed through to the diseased part by Hey's saw. So also at upper end. Then by chisel and mallet the portions of newly-formed bone lying over the diseased bone were removed. The edges were afterwards removed by a gouge and the bone nippers, so that the diseased portion might be removed, which was then done, the lower part of it being first raised by the levator; then the bone drawn down, as it extended a little under at upper part, and was removed. Wound was then cleansed and all parts adjusted. Compresses applied, and a roller passed around. Considerable loss of blood, faintness and vomiting during the operation; and at the termination of the operation, faintness, which lasted for some time. Was cold. Hot water and spirit was applied to the extremities, and brandy with water as freely as she could bear, with the occasional addition of six drops of ammoniated alcohol. She revived, but continued much exhausted, and became delirious. Pulse extremely rapid and feeble. Had several faint turns in the evening, with catching for breath. Hot baths and bottles were continued, with internal stimulation. She finally sank, and died at half-past nine in the evening, from the exhaustion, irritation and shock of operation, her constitution being delicate and very irritable."

An operation for the removal of a tumor of the lower jaw. Incision carried from the cheek-bone down over jaw and two inches below, in a semicircular line. A second incision meeting the extremes of the first was made, and part of the skin, etc., included, removed. The parts covering the bony tumor were then carefully dissected up on the exterior and also on the interior parts. It was then found necessary to remove two teeth from the jaw. The surgeon then proceeded to divide by Hey's saw the middle, about one and one-

half inches from the point of the chin. The bony tumor was then, by means of the levator and with some difficulty, raised; in doing which the bone gave way in the diseased part. This portion was then removed. The remaining part was then separated from the muscles covering it, and with considerable difficulty detached at its articulation, the ligaments, etc., being exceedingly firm. The facial and maxillary arteries were secured by ligature, the wound cleared and brought together. Sponges were laid upon the parts, also a compress followed by a roller. Loss of blood inconsiderable. Had some faintness at times, but bore the operation well. Tumor size of large egg.

A patient with symptoms of stone. After giving one hundred drops of laudanum, the patient was placed on the table with hands bound to feet and legs drawn up. The usual lateral operation was performed, and a stone of the size of an egg removed. Patient bore the operation well.

Cancer of penis. "Penis held fast, divided about an inch from the pubes by one stroke of the knife."

Cancer of the breast. Two semicircular incisions of five or six inches. The gland carefully dissected out. The glands of the axilla, being schirrous, were dissected out, in the course of which the axillary vein was opened. It was closed by compression.

The following brief histories appear:

January 7, 1825. "Breast was cut out with the integuments over it and the glands of the axilla."

February 4th. "Hemorrhoids cut off."

Cancer of penis. "Eighty drops of laudanum before operation. Amputation."

Up to June 26, 1826, when erysipelas was first mentioned in the records, wounds had behaved admirably, many healing by first intention, and the admissions had included many severe injuries, such as burns (largely lacerated wounds) followed by foul and suppurating discharges. The "erysipelatosus affection" became so troublesome that all of the staff were requested by the trustees to propose measures fitted to eradicate the disease. They proposed the vacation of the hospital from four to six weeks. Those already sick to be isolated, and those who could bear removal to be sent to an adjoining house that could be hired for the purpose. All clothing and beds to be washed or baked. Old straw to be thrown away. The hospital wards to be exposed to the fumes of burning sulphur for three days, and one day to the strongest fumes of chlorine; then to a free current of air for at least one week, day and night. In the mean time all the sick-rooms to be whitewashed. The cellar to be thoroughly cleansed.

For the prevention of a return of this calamitous occurrence, they propose that the number of beds be diminished one-third from the late establishment, and never to be increased beyond this without a formal order from the trustees upon consultation with the Medical Board; that fireplaces be constructed where it is possible; that the water-closets be more thoroughly ventilated; and that in case of any further appearance of erysipelas the patient shall be moved out of the hospital, and everything about him removed or thoroughly disinfected.

It shall be the duty of the medical officer having such cases to report them at once to the superintendent, who shall be directed to remove such patient to some proper place without delay.

JOHN C. WARREN,
WALTER CHANNING,

JAMES JACKSON,
GEORGE HAYWARD.

On December 28, 1827, catgut ligatures were used for the first time. The patient was a woman with a tumor of the meatus urinarius.

In preparation for an amputation on September 20, 1832, the patient received at 10 A. M., pulv. opii, gr. ii; at 10.30, tinct. opii, gtt. xxx; at 11, tinct. opii, gtt. xx; without much effect.

Dislocation of the hip. The patient was admitted October 9th. From that time to the 17th, he was given saline cathartics and a light diet. On the 18th, at 10 A. M., tartrate of antimony, one grain, and repeat every twenty minutes; omit when nauseated. At 20 minutes past 10, warm bath at 100°, increased to 110°; to remain in it one half-hour.

Patient being placed on the operating table, the cords and pulleys were attached to the dislocated limb. The fourth dose of antimony produced nausea. The vein in the left arm was opened. At this time (11.40) the extension commenced. At eight minutes before twelve o'clock faintness and great prostration. The extension was steadily continued by one person. A lengthening of the limb was perceptible. Complaint of pain in the vicinity of the head of the bone. The limb was rotated inwards across the left thigh. It now appeared longer than the sound one. A broad bandage was now placed around the upper part of the thigh, passing across the shoulder of an assistant. A belt was passed around the pelvis, thus making a counter-extension to the broad bandage. The limb was again rotated inwards. No success following this direction, and the head of the bone appearing to be on the edge of the acetabulum, the limb was rotated upwards and outwards. At this time, twenty minutes before one o'clock, the patient exclaimed, "It is in!" The motion was felt by Dr. Warren while rotating, and by Dr. Hayward, whose hand was on the cervix. It was a success.

December 6, 1829. During the removal of a tumor of the lower jaw the bleeding became so profuse that it was necessary to apply the actual cautery. This checked it for a while; but as it recurred after reaching his room, it only stopped when he fainted. Five days after he had more hemorrhage, arrested by styptics.

The first case to be classed as abdominal, excepting strangulated hernias, etc., was that of a woman who entered the hospital October 28th, aged forty,⁵ with an abdominal tumor that had grown from the size of a goose-egg until it extended from the right groin to the false ribs of that side, measuring fourteen inches in that direction. It was first noticed on the same side, below and to the right of the umbilicus. Tumor movable, not tender, very firm and not fluctuating. Urine, thirty ounces, natural. No disturbance of functions. No pain. General health, appetite, and sleep good. Catamenia regular and profuse during the past ten years. Vaginal examination shows os high up above symphysis. Not tender or enlarged. Uterine fundus and body felt upon rectal examination. No tenderness or compression of gut. Enema at 10 A. M., and thirty drops of laudanum at 10.30. Operation at 11.

Directions for operation: Patient to have sixty drops of laudanum. Theatre heated carefully to 70°. Rain-water of blood-heat, and soft cloths to cover intestines. Usual instruments for an extensive operation.

Dr. Warren operated by an incision through the integuments in the linea alba, beginning three inches below the umbilicus and extending downward four inches. Subjacent muscles then carefully divided and the peritoneum opened, exposing the surface of the tumor to view. An attempt now made to reduce the size of the tumor by puncturing it with a trochar and canula. No fluid followed. It was found necessary to enlarge the incision upwards above the umbilicus. Tumor was then brought through the wound without difficulty, as it adhered only at its base. A strong cord was then tied firmly around the neck of the tumor, great care being taken to avoid including any of the intestines and to diminish the loss of blood. On cutting partly through the neck, the divided parts were found to retract, by reason of which the ligature was loosened. Another was accordingly passed around the undivided portion of the tumor, and it was then completely removed. Attempts were then made to stop the flow of blood, and several arteries were tied. After this object had been nearly or quite accomplished, the patient was found to be quite faint. Cold water was dashed upon her face, and brandy and water poured down her throat. Brisk friction of her limbs and application of blankets dipped in warm water were also made. The patient not reviving, artificial respiration was kept up for some time by inflating the lungs with a pair of bellows. The stomach-pump was then brought, and half a pint of hot brandy thrown into the stomach; but all these attempts proved fruitless, and the patient was finally given up for dead.

One of the popular methods of treating sore eyes among the public at that time was to apply a *frog that had been broiled alive in a pound of butter*. A patient entered who had found this a valuable remedy; but in spite of its efficacy he was unable to open his eyes without force.

Amputation of the thigh, May 25, 1839. "Patient had one hundred drops of laudanum. He thinks that he did not feel the opium until after the operation."

Tumor of the tongue. Tumor being grasped by double hooks, it was removed by one stroke of the scalpel. Hemorrhage considerable; not being controlled by ligature, the actual cautery was applied. At 4 P. M., another hemorrhage; compression by sponges. At 5 P. M., another hemorrhage, controlled by sponge.

During an enucleation the eye was grasped by the forceps in the same way.

Removal of tongue. Tongue being protruded, it was seized with a long-bladed polypus forceps, transversely behind tumor, and firmly compressed. Tumor then being seized between the left thumb and forefinger of the operator, a straight, sharp-pointed bistoury was passed across behind tumor through the healthy portion of the tongue, and the two lingual arteries secured by ligatures. Little blood was lost. Patient bore the operation with great fortitude.

An extensive, malignant, ulcerating growth involving the labia, nymphæ, clitoris and urethra in a woman of twenty-nine years. A careful dissection was made of the whole ulcerating surface. Great pain and persistent syncope accompanied the protracted dissection.

A long story of agony and blood, to which man was born from earliest prehistoric time; the shadows of which were lightened by the results of brilliant operations that restored life, health and limbs to the dis-

abled and unfortunate, and by the opportunities for teaching the way of saving lives to others. So far as humanity could suggest remedies or the science of the times permit, pain was relieved. The terrors of the past, which had cast their gloom over hospitals and surgeons alike, restricting the natural growth of science, that held in its grasp the suffering and mortality of millions waiting for its beneficent protection, were dispersed and shorn of their sting by the light shining from this Temple of Health on October 16, 1846. That light has been reflected to the surgery of the whole world, comforting the sufferer, arming the surgeon, and illuminating the pathway of Science throughout the Universe of Pain.

"The heart of every American physician is filled with thankfulness when he remembers that, in the providence of God, this great boon to humanity was vouchsafed to this country. The very ground upon which stands the Massachusetts General Hospital is sacred to us all."⁶

Recent Literature.

Medical Jurisprudence, Forensic Medicine and Toxicology. By R. A. WITTHAUS, A.M. M.D., Professor of Chemistry, Physics and Hygiene in the University of the City of New York, etc., and TRACY C. BECKER, A.B., LL.B., Counsellor-at-Law and Professor of Criminal Law and Medical Jurisprudence in the University of Buffalo. With the aid of numerous collaborators. In four volumes. Vol. IV. New York: William Wood & Co.

In a notice of the first volume of this comprehensive work, the JOURNAL said that if the standard of excellence illustrated in that volume was continued in those to follow it, the two professions of law and medicine would have at their disposal an encyclopedic production of the highest character. And now that the final chapter has been written and the last volume of the series has come from the press, it gives us pleasure to declare that our early anticipations have been realized, to congratulate the editors and publishers upon the completion of their task, and to express a candid and cordial appreciation of the publication as the best treatise on Legal Medicine which is now available in the English language. In scope, in the intelligence shown in the treatment of the many topics, in the discrimination with which the latest advances in medico-legal knowledge have been used, these volumes represent a success of which their projectors may well be proud.

This fourth, and final, volume is devoted exclusively to Toxicology and is the sole work of Professor Witthaus. The same purpose dominates this book as has found expression in the three earlier volumes in the series, namely, to gather and present whatever, relating to the subject, was most useful to the two professions for which the whole work was designed. After an interesting review of the literature and history of poisoning, setting forth the indefensible manner in which royal personages and popes, as well as people of lower degree, have used poisons to rid themselves of une congenial acquaintances, the author wrestles acceptably with the question, "What is a poison?" A considerable section is devoted to topics

⁶ Dr. W. W. Dawson: Life of Ephraim McDowell.

pertaining to general toxicology; and, finally, in special toxicology, the author gives full attention to the various known toxic agents, their chemistry, symptomatology, anatomical effects and detection in the tissues by analytical determination. The whole field of poisons is included, emphasis and prominence being bestowed on individuals in that class where these are justified.

Our space will not permit detailed mention, and we content ourselves with the general statement that the volume is a treasury of learning at which the seeker after help will find his drafts fully honored.

Skiascopy and its Practical Application to the Study of Refraction. By EDWARD JACKSON, A.M., M.D., Professor of Diseases of the Eye in the Philadelphia Polyclinic; Surgeon to Wills' Eye Hospital, Etc. Philadelphia: The Edwards & Docker Co.

The fact that the first edition of Dr. Edward Jackson's excellent monograph on "Skiascopy and its Practical Application to the Study of Refraction" was sold within the first year of its existence, bears witness to its popularity, and is the reason for the issue of a second edition. The changes that are noticed are slight, being mostly alterations in the phraseology, resulting in greater clearness of expression.

This valuable addition to the methods of objective diagnosis is treated in accordance with its importance, so that the careful reader must realize that skiascopy will be found of use only as its underlying principles are applied.

To those who have employed the "shadow-test" without a clear idea of the optical principles upon which it is based, this treatise may appear somewhat too diffuse; but whoever adopts the author's routine in examining, and becomes thoroughly acquainted with each step and the reason therefor, will not find any superfluous matter.

When beginning to study the tests it is advisable to start with known conditions of refraction, with lenses of known strength, and with the eye at a known distance, thus becoming familiar with the behavior of the light and shadow in the pupil under such conditions that in ametropia it will be possible to deduce from the pupillary appearances the state of the refraction which causes them. Great stress is laid upon the position of the light, and its most advantageous arrangement. The advantages and the disadvantages of the plane and concave mirror receive careful consideration, and explicit directions regarding the best manner of constructing the mirror are given. Other details, which in the author's wide experience would seem to him to be of value to the oculist or practitioner, have not been omitted.

It is truly a pleasure to be able to recommend so excellent a book upon so important a subject.

Water and Water-Supplies. By JOHN C. THRESH, D.Sc., M.B., D.P.H. London: The Rebmam Publishing Co. 1896.

The main object of this book, as the author states, is "to place within the reach of all persons interested in public health the information requisite for forming an opinion as to whether any supply, or proposed supply, is sufficiently wholesome and abundant, and whether the cost can be considered reasonable."

This book contains twenty-three chapters, the first

seven being devoted to the different kinds of water and water-sources; these are followed by chapters upon impure water and its effect on health, interpretation of analyses, the self-purification of rivers, purification of water, domestic purification, the softening of hard-water, wells, pumps, pump machinery, water storage, distribution, etc.

The writer makes frequent reference to the experiments and investigations of the Massachusetts Board of Health, as a standard authority upon the subject.

This volume will be found to be a very useful manual for reference by young engineers, water-boards, superintendents and sanitary authorities.

The Tonic Treatment of Syphilis. By E. L. KEYES, A.M., M.D., Late Professor of Dermatology, Syphilology and Genito-Urinary Surgery in the Bellevue Hospital Medical College; Consulting Surgeon to the Bellevue Hospital. Revised edition. New York: D. Appleton & Co. 1896.

While thoroughly believing that the curative power of mercury in syphilis is due to its specific action on the disease, and from time to time as the symptoms demand it must be pushed to the point of mercurialization, the writer has found that in addition to its specific action, mercury in small doses acts directly as a tonic, by increasing the number of red corpuscles in the blood. He has demonstrated the fact of this increase of the red corpuscles on numerous patients who have been under his treatment by small doses of mercury for long periods, by actual blood-count, and has found that coincidently with the increase in the number of red blood-corpuscles, as shown by the hematometer, a marked improvement took place in the patient's general condition.

The iodides, also, he has found to possess a tonic action in addition to their antisiphilitic effects; but his experience coincides with the generally accepted view that they have very little effect on the disease in its earlier stages, being of use in the treatment of the gummatous tumors and chronic cutaneous affections of the later stages of the disease.

His plan of treatment is to give mercury up to the full dose until the earlier manifestations of the disease are controlled, and then to continue its administration in minute doses over long periods as a tonic.

The latter part of the book is devoted to a discussion of the details of the author's methods of treatment of the general and special manifestations of the disease. He does not consider it safe to suspend the mild mercurial course under two and a half years. Intramuscular injection is the method of administration of mercury to which he gives preference.

The book gives explicit directions for the treatment of the various stages and lesions of the disease, and is well fitted for a practical reference book for practitioners who may desire to inform themselves on the subject.

The Physician's Visiting List, 1897. Philadelphia: P. Blakiston, Son & Co.

We are glad to acknowledge the receipt of the above familiar visiting-list, now in the forty-sixth year of its publication. A better testimonial to its merits could hardly be given than its continued yearly appearance. We recommend the list to all general practitioners. They will find it suitable, and certainly most useful in the conduct of their daily practice.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, JANUARY 7, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

RECOLLECTIONS OF SURGERY BEFORE AN-
ESTHESIA.

THE great interest which was excited among the profession in this country and in Europe in the Jubilee of Anesthesia held October 16th last, has brought out a host of recollections of the great event itself, and of the period which immediately preceded it.

The number of men who are able to recall that period is, however, a rapidly diminishing one, and the time is near when those who witnessed the cries and struggles of the amphitheatre will have all passed away.

The history of those times has never been written, and the coming generation of surgeons will never know what the ordeals of surgery without anesthesia really were, unless those who still remember them shall record their experiences.

Of the series of papers published in the JOURNAL to-day, that by the venerable Dr. Markoe gives a glimpse of the period when the new era was about to dawn upon New York. The selection from the old records of the Massachusetts General Hospital, by Dr. Beach, throws a curious side-light among many other interesting facts, upon the attention to details which seemed important in those days and now so useless.

The contributions of Drs. Cotting, Wheeler and Bemis have the flavor of the period of the middle of the century, and are the records of men who were a part of those times.

Dr. Ingalls's article is of special value, as it covers, as it were, at one leap the extremities of this century, and is the personal experience of one of the few surgeons of those times still living with us.

It is high time that the material which such men can afford the future medical historian of that era should be collected, as the generation which witnessed those stirring scenes will have soon passed away.

In this connection it is well to note with satisfaction the universal recognition of the great historic event of the birth of surgical anesthesia, and that the occasion

was celebrated on the same day, October 16th, not only in Boston, but Eastward as far as Moscow, and Westward as far as Minneapolis. The general recognition given by English surgeons, of the significance of this event, cannot be otherwise than gratifying to all American surgeons.

MEDICAL EXPERT TESTIMONY IN HYPOTHETICAL CASES.

A WELL-KNOWN lawyer, when asked his opinion of the value of medical expert testimony in hypothetical cases replied that it served a purpose in showing the utter worthlessness of the medical testimony on the other side. He admitted, of course, that his own experts were open to a similar criticism, but said that the jury balanced the one against the other and considered the result as being equal to zero.

Between the rules of evidence in court on the one hand, and the desire of the lawyer, on the other hand, to make out the best possible case for his client, the physician may be placed in an embarrassing, or even compromising, position, or else feel obliged to decline to give the courts the benefit of his experience in such cases. The lawyer, too, may be driven by his opponent to think that he must rebut certain testimony by using the hypothetical question under most unsatisfactory conditions, which many physicians might regard as not preventing them from accepting the situation for what they considered a good enough purpose.

But even here, we think that both lawyer and physician may make a mistake. Not long ago, a lawyer contesting what was regarded as the insane will of an insane person was confronted with the unexpected appearance in court of two physicians who on a hypothetical question testified to the man's sanity. The lawyer desired another physician to go at once to court and contradict these opinions and was rather surprised at his saying that it would be impossible for him to place himself in such a position. The advocate was advised, however, to tell the jury that the question of the soundness or unsoundness of mind in the case before them was one of facts and not of opinion; that they were even better able than the physicians to pass upon the facts, which seemed plain, inasmuch as their position was an impartial one and that of the physicians prejudiced, because the physicians had been employed by the defence, and examined and cross-examined, in such a way as to make it very difficult for them to avoid giving one-sided testimony. The lawyer followed the physician's advice, for which there was no fee, and gained his case.

It is not easy for medical men to estimate the weight of various kinds of evidence on the minds of the jury. We cannot but believe, however, that in the case recently tried in Boston, there was an excellent opportunity for the government to use such an argument with telling effect, and at the same time to relieve the medical profession from an embarrassment for which it has received less credit than fairly belongs to it.

The lawyers know that some physicians think that they may act as medical counsel for any client and, like his advocate, make out as good a case as they can for him, irrespective of what would be their opinion if given in an entirely unbiassed way. Others are so judicial-minded or scientific in their attitude, and so fair in their statements, that it has happened that lawyers finding them summoned by their opponents have not found it necessary to call other experts to contradict them, because they trusted to their fairness, intellectual and moral.

Physicians who respect themselves and who wish their profession to be respected have not thus far been able to suggest any complete remedy for what is generally admitted to be a most deplorable state of things; the lawyers seem equally at sea, and the courts, following rules and precedents, cannot exclude testimony which is by both admissible.

Until some reform is begun, the medical profession can only depend upon itself to act with dignity and self-respect in individual cases, and, as a body, to make its approval or disapproval felt as to general practices.

THE RATES OF MORTALITY IN NEW ZEALAND.¹

THE populations of the colonies of British Australia and other neighboring regions present features of unusual interest, and the reports from these colonies compiled in recent years are unusually full of valuable statistics.²

The census examinations of the population of New Zealand, of European descent, taken at irregular intervals, shows a rapid increase from a total of 26,707 in 1851 to 626,658 in 1891. The males were in excess at each enumeration, and were in the ratio of 1,288 males to each 1,000 females in 1851, and 1,133 to each 1,000 in 1891.

The population has increased, not only in consequence of immigration, but in consequence of the excess of its birth-rate over its death-rate. For the whole period of forty years the deaths were less than one-third as many as the births. Added to this is the fact of a low mortality of infants, the deaths under one year being generally less than ten per cent. of the births. This high birth-rate, and low infant-mortality has a marked effect upon the age-constitution of the people, as the following figures will show:

PERCENTAGES OF POPULATION AT CERTAIN AGES.

	New Zeal. 1881-91.	Eng. and Wales, 1891.	Mass. 1865-99.
Birth to four years . . .	14.	12.3	9.9
Birth to fourteen years . . .	41.1	35.	28.8
Five to fourteen years . . .	24.5	22.8	18.8

The result of this unusually large ratio of persons at ages of life when the death-rate is low (five to fourteen years) is to produce a low death-rate at all ages.

¹ Reprint from the New Zealand Journal of Insurance, Mining and Finance, November, 1895. Quarto, 16 pp. By George Leslie, Assistant Actuary, Government Life Insurance Department, etc.

² See, for example, the Victorian Year Book.

The population at ages beyond sixty is also correspondingly small.

Mr. Leslie constructs from his census enumerations and the vital statistics of the colony, a life table for New Zealand; and if the figures may be relied on (which we have no reason to doubt), it would appear that no more healthful region has yet been found. The general death-rate of the population for the years 1880 to 1892 was never higher than 11.5 per 1,000, and ranged between 11.5 and 9.5 during that period.

The table giving the probabilities of living for the first five years of life shows that the New Zealand child has a greater probability of living than the children of the same ages in the Australian Colonies or in the healthy districts of England, and nearly as great as the children of the English peerage (a selected class).

The ratio of males to females at birth in New Zealand is as 1,045 boys to 1,000 girls, the number of the former during the thirteen years 1880-1892, exceeding the latter by 5,381. But the deaths of boys under five during the same period, exceeded those of girls of the same age by 2,737, so that fully one-half of the difference in the sexes had disappeared before the fifth year of life was begun.

Since the general death-rate is shown to be low, it follows that the rate from special causes is also generally low. The following table shows the death-rates per 10,000 of the population from different causes in New Zealand:

ANNUAL DEATH-RATES PER 10,000 LIVING, FROM CERTAIN CAUSES, NEW ZEALAND AND MASSACHUSETTS.

	New Zeal. 1885-94.	Mass. 1855-94.
Measles	1.03	1.0
Scarlet fever23	2.2
Whooping-cough	1.8	1.2
Diphtheria and croup	2.9	7.4
Typhoid fever	2.14	3.8
Small-pox	0.0	.04
Cancer	4.5	6.0
Consumption	11.2	26.1

It appears from Mr. Leslie's statements that the colony has been exempt from small-pox since the English occupation of the island in 1840.

It appears also from the foregoing figures that the death-rate from the principal infectious diseases is generally less than that of Massachusetts, the exceptions being measles and whooping-cough. The death-rate from violent causes, and especially from suicide, is greater than that of most civilized countries.

MEDICAL NOTES.

ANTITOXIN IN LOUISIANA.—The Louisiana State Board of Health has announced that it will supply antitoxin free of charge to poor diphtheritic patients.

SIR JOSEPH LISTER RAISED TO THE PEERAGE.—Sir Joseph Lister, who was raised to the peerage on New Year's Day, is the first physician to receive that honor. The discovery and application of surgical asepsis gives reason enough for the bestowal of this extraordinary distinction.

ROUX DIFFERS FROM PASTEUR. — Dr. Roux has accepted a decoration from the German Emperor. Pasteur, it will be remembered, declined a similar proffered honor.

INTERNATIONAL MEDICAL CONGRESS. — The managers of the surgical section of the Twelfth International Medical Congress to be held in Moscow, Russia, in August, 1897, have invited Dr. Stephen Smith to accept an honorary presidency and preside at one session of the section.

A MEDICAL PRESIDENT. — M. Adolphe Deucher, who has just been elected President of the Swiss Confederation for the ensuing year by an almost unanimous vote, is a member of the medical profession. He was born in 1831, and was actively engaged in medical practice till the year 1879, when he retired in order to devote himself entirely to political life.

PLAGUE IN LONDON. — Two cases of plague have occurred during the autumn in a sailors' hospital in London, both being sailors recently arrived from Bombay. This ought to settle once for all the question whether plague is carried to long distances by sea, and increase the probability that the Bombay outbreak was communicated by sea from Hong Kong.

PHILADELPHIA PEDIATRIC SOCIETY. — More than one hundred physicians met at the College of Physicians, Philadelphia, on Tuesday, December 22, 1896, to organize the Philadelphia Pediatric Society, "for the study of disease in children, in all its branches." A Constitution and By-laws were adopted, and the following officers elected: President, Dr. J. P. Crozer Griffith; Vice-Presidents, Drs. Edwin E. Graham, Arthur A. Meigs, Frederick A. Packard; Secretary, Dr. Alfred Hand, Jr.; Treasurer, Dr. C. F. Pettibone; Executive Committee, Drs. Alfred Stengel, J. Madison Taylor, Chas. W. Burr, Wm. B. Atkinson, Thompson S. Westcott. The membership list is a large one, including many of the prominent physicians of Philadelphia and vicinity.

PROFESSOR ERISMANN COMPELLED TO LEAVE RUSSIA. — Dr. Erismann, professor of hygiene in the University of Moscow, who was chosen general secretary of the organization committee for the coming International Medical Congress of Moscow, has been obliged, on account of what the government considered his too liberal ideas, to resign his position, and leave Russia; he has taken up his residence in Switzerland. Dr. W. K. Roth has been appointed general secretary in his place. Professor Erismann was sent by the Russian Government as one of the chief official delegates to the International Medical Congress in Berlin, in 1890. He was senior professor at Moscow. According to the *British Medical Journal*, sympathetic expressions of regret in the Russian papers have been suppressed, and the medical and lay press has been positively forbidden by the chief of the department for press regulations to express any sympathy with him in any form whatever.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, December 30, 1896, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 83, scarlet fever 29, measles 127, typhoid fever 21.

A CENTENARIAN. — The one hundredth birthday of Mrs. Chloe Fales Adams Metcalf was celebrated at her home in Walpole, Mass., on January 1, 1897.

DEATH AT THE AGE OF ONE HUNDRED AND THREE. — Catherine Perry, of New London, Conn., died December 29th, aged one hundred and three.

DEATH OF A CENTENARIAN. — Miss Miranda Herick died in Willimantic, Conn., December 31st, aged one hundred and one years.

OPENING OF THE BROOKLINE PUBLIC BATH. — The new Brookline (Mass.) Public Bath was opened with an interesting swimming and water-polo exhibition on January 1st and 2d, by professional swimmers, and members of the Brookline Swimming Club. All who were present were impressed with the beauty and admirable arrangement of the new building and its excellent appointments in every particular.

THE ANNUAL MEETING OF THE AMERICAN PHYSIOLOGICAL SOCIETY. — The Ninth Annual Meeting of the American Physiological Society was held in Boston, December 29th and 30th. The meetings were held at the Harvard Medical School and at the Harvard University Museum at Cambridge, and numerous interesting and valuable papers were read. On December 29th, Mr. Alexander Agassiz delivered a lecture before the Society at the Fogg Museum of Art, Harvard University, Cambridge, and received the members at his house after the lecture. On December 30th, Prof. E. B. Wilson lectured before the Society at the Fogg Museum, on "Recent Developments of the Cell Theory," and after the lecture the President and Fellows of Harvard College entertained the members at lunch. In the evening the Annual Dinner of the societies of Physiologists, Morphologists, Psychologists and Naturalists was held at the Hotel Brunswick, Boston, after which followed the address of Prof. W. B. Scott, President of the American Society of Naturalists.

MARRIAGE AT ADVANCED AGE. — The report of a recent wedding in Maine, at which the bridegroom was ninety-seven and the bride eighty-seven years old, is only surpassed by the account of a Kentucky wedding in which the bridegroom was aged one hundred and three and the bride one hundred and one. It is a little singular that both these weddings took place in leap year. Whether this fact has any significance or not, it looks as though a man might meet his fate at any time between sweet sixteen and sweet one hundred and one. Our old bachelors had better not boast of their contentment with single blessedness until they have successfully weathered the century mark. However, by next leap year, all centenarian bachelors and

maids will be aged one hundred and eight, which can probably be fairly considered, for the present at least, beyond the danger limit.

ANNUAL REPORT OF THE CHILDREN'S HOSPITAL. — The Annual Report of the Boston Children's Hospital shows that during last year, the twenty-eighth year of its existence, 779 patients were treated in the wards, 2,959 in the out-patient department, and 343 at the convalescent home, making the total number treated during the year 4,081. Antitoxin has been given as a prophylactic against diphtheria as a routine measure to all children entering the institution, with the result that only one case of diphtheria originated during the year, and that in a case where the antitoxin was unavoidably omitted. The report closes with an appeal for funds to carry on the work.

A TOWN ENSLAVED BY THE COCAINE HABIT. — It is reported in the daily papers that so large a number of the inhabitants of the town of Manchester, Conn., have become slaves to the cocaine habit, that in the opinion of an "experienced physician," "the future prosperity of the town is involved." The trouble arose from a preparation of cocaine and menthol which a druggist in the town compounded about a year ago, and exploited as a remedy for asthma. So popular has this "snuff" become that people are seen in the streets and in dark corners at public entertainments indulging their passion for the compound. According to the report, the druggists, although getting rich by the sale of the compound are so bothered by "well-known men and women" who ring them up at all hours of the night to obtain a supply, threatening to break into the store if their wants are not attended to, that they have become prime movers in an attempt to check the evil habit. Large numbers of the people are apparently running into debt to provide themselves with this expensive drug and, if the story is true, we must acquiesce in the reported remark of a druggist, who says, "their condition is pitiable." A drug habit which will drive "well-known men and women" to threaten violent entrance into drug stores must be indeed a difficult problem for the town authorities to cope with.

NEW YORK.

DEATH OF DR. NEWMAN. — Dr. William Newman died at his residence in Brooklyn on December 31st, aged seventy-six years and six months. Dr. Newman was a licentiate of the Medical Society of the State of New York in the year 1874, and practised both in Brooklyn and New York, having an office on East Grand Street in the latter city.

DR. SHAFER'S LECTURES. — The Trustees of the New York Orthopedic Dispensary and Hospital announce that Dr. Newton M. Shaffer, surgeon-in-chief, will give his twentieth annual course of clinical lectures on orthopedic surgery at the institution on Monday and Thursday afternoons during January and February. These lectures are free to the medical profession and students.

A CHRISTMAS PRESENT TO ST. MARK'S HOSPITAL. — A pleasing feature of the Christmas celebration at St. Mark's Hospital, on Second Avenue, was the presentation to the institution of a check for \$5,000 by Mr. Ruttanan, one of the directors.

LOW DEATH-RATE IN DECEMBER. — The bulletin of the State Board of Health for November states that the number of deaths reported in the State during that month was only 7,888. This represents an annual death-rate of 14.74, which is the smallest recorded for ten years. The total number of deaths was 500 less than in November, 1875.

TYPHOID AT A NURSES' TRAINING-SCHOOL. — A somewhat serious outbreak of typhoid fever is reported at the training-school for nurses of Mount Sinai Hospital. The school is one of the largest in the city and twelve out of sixty-six pupils have been attacked with the disease. The hospital authorities have been endeavoring to make a thorough investigation of the origin of the outbreak, but the result has not as yet been announced.

COMPLETION OF THE NEW BUILDINGS OF ST. LUKE'S HOSPITAL. — On December 28th a gold medal was presented by the American Numismatical and Archæological Society to the Board of Managers of St. Luke's Hospital, in commemoration of the completion of the new hospital buildings at Amsterdam Avenue and 113th Street. The medal has on one side a medallion of the Rev. Dr. Muhlenberg, founder of the institution, and on the reverse an appropriate inscription.

THE POLYCLINIC HOSPITAL DESTROYED BY FIRE. — One of the largest fires that has occurred in New York in months took place on Christmas day, and among the buildings destroyed was the New York Polyclinic Medical School and Hospital. Fortunately the fire occurred in the day-time, and all of the sixty patients, some of whom had just undergone severe operations, were successfully rescued. A fire, of a less serious nature, also occurred on the same day at the St. John's Guild Hospital for Children on West 61st Street, in which there were some forty patients.

THE NEW ANNEX OF THE ORTHOPEDIC HOSPITAL. — The Board of Supervisors and the Trustees of the New York Orthopedic Dispensary and Hospital, in East 59th Street, held their annual reception on December 21st, and on this occasion the recently completed annex to the hospital, with its operating-room, roof-garden, play-room and cheerful wards, was thrown open to inspection. In his address the President, Mr. O. Egerton Schmidt, stated that the improvements were largely due to the generosity of a lady, who withheld her name, who last summer gave \$37,000 to the institution. An important feature of the new annex is a complete Röntgen-ray apparatus, and in his remarks Dr. Newton M. Shaffer, the surgeon-in-chief, who was also one of the speakers, dwelt upon the material assistance rendered to orthopedic surgery by this discovery.

DEATH OF DR. WALLACE.—Dr. William Wallace, one of the best known physicians in Brooklyn, died at his residence in that city on December 22d, after a brief illness. He was born in Ireland in 1835, but was educated in Scotland, and was a graduate of the University of Edinburgh. He received his medical degrees from the Royal College of Surgeons in 1856, and the Royal College of Physicians in 1860. He served as an assistant surgeon in the British Navy during the Crimean War, and afterwards became ship's surgeon in the Cunard Steamship Company. He settled in Brooklyn in 1864, and has practised there ever since. At the time of his death he was a member of the Council of the Long Island College Hospital and physician to St. John's Hospital and the Home for Consumptives. He leaves a widow and two sons.

Correspondence.

CAMDEN, S. C., AS A HEALTH RESORT.

CAMDEN, S. C., December 22, 1896.

MR. EDITOR:—Thinking that some of your readers might be glad to learn the particulars about one of the Southern winter resorts, I will give some of my impressions of Camden, S. C., and the Hobkirk Inn where I have brought friends to pass the winter.

The soil of Camden and vicinity is sandy. The town is situated at the foot of Hobkirk Hill, a slight elevation from which the land slopes very gradually towards the river, which runs west and south of the town. The town is well ditched, so that with the sandy soil the drainage is very good. Dr. Moore tells me that there have been only five or six cases of typhoid in this section during the past year. The inn itself is an old manor-house with open fire-places, both in the great square rooms of the old house and in the more recently built wings. There is no furnace or steam to make the air dry as a lumber kiln.

The cordial welcome and persistent attention of the proprietor, Mr. F. W. Eldredge, and the cheerful appearance of the entrance-hall and parlor at once permanently dispel any doubts which may have arisen in one's mind during the last sixty-mile ride through the barren cotton-fields as to the advisability of having separated one's self from home comforts.

The sanitary arrangements are good, the earth-closets being cleaned and their contents removed each day. The water from the bath-room and kitchen is carried away from the house into one of the ditches at a distance in the field, and the rubbish heap is cleared out each week or oftener as demanded.

Water for the house is furnished by a well just back of the inn, but the drinking-water by a well in the side garden. This well is bricked and cemented to the very bottom so that nothing can get in from the sides, and thirty-five feet of sand ought to guarantee good filtration for the water.

There are broad piazzas and good walking in the garden and immediate neighborhood. Walks and drives are not specially interesting, as there is but little variety to the scenery of the broad, brown cotton-fields, and the roads are soft and sandy. Bicycling about the town is fair, but it takes a good deal of courage to leave the limits of the sidewalks on which you ride. Horseback riding I have not tried, but apart from the sandy roads must be pleasant, for there are roads interlacing in all directions, going into the woods and around the swamps.

In the warm part of the day the air is not at all enervating. The temperature has been about 40° each morning at breakfast time, yet there has been none of the sharp

frosty feeling in it which characterizes our late October mornings. The soil is so porous that the water quickly disappears, and there is hardly a suggestion of mist the morning after even a heavy rain in the night.

The reports of the National Climatological Society, I believe, give the matter of temperature of Camden for a number of years, but, if I am not mistaken, there have been no accounts of what is practically the most important feature of a health-resort, the humidity, so I will append the following table which has been kept by Mr. E. H. Townsend, of New York:

AVERAGE RELATIVE HUMIDITY OF CAMDEN.

1893. January, 62%; February, 64%; March, 54%; April (16 days), 52%.
1894. January (20 days), 60%; February, 65%; March, 54%; April (18 days), 54%.
1895. January (21 days), 50%; February, 55%; March, 64%; April (23 days), 54%.
1896. January (20 days), 63%; February, 57%; March, 50%; April (5 days), 38%.

The above is interesting as giving the relative humidity for just those portions of the year in which Camden is useful to Northern visitors and not an average humidity, including the hot, dry summer. The mid-day observations for the past two years will also be of value as giving the condition of the atmosphere for the out-of-door period of the day:

1895. January, 53%; February, 50%; March, 53%; April, 47%.
1896. January, 57%; February, 47%; March, 40%.

Just one thing more. As Kipling says.

"But the backbone of the army is the non-commissioned man!"

So the backbone of a hotel is its cook, and "Mis' Ella" leaves nothing to be wished for. Very truly,

A. K. STONE, M.D.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, DECEMBER 26, 1896.

Cities.	Estimated population.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from					
				Infectious diseases.	Acute lung diseases.	Diarrheal diseases.	Typhoid fever.	Diphtheria and croup.	
New York . . .	1,892,332	603	130	8.84	17.17	.68	1.19	5.78	
Chicago . . .	1,678,967	400	183	13.00	25.25	3.50	3.50	6.25

Deaths reported 2,511; under five years of age 797; principal infectious diseases (small-pox, measles, diphtheria and

croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 238, acute lung diseases 405, consumption 279, diphtheria and croup 148, typhoid fever 47, diarrheal diseases 35, scarlet fever 27, measles and whooping-cough 13 each, erysipelas 11, cerebro-spinal meningitis 4.

From scarlet fever Boston 10, New York 5, Philadelphia and Baltimore 3 each, Chicago, Pittsburgh and Cambridge 2 each. From measles New York 7, Chicago, Boston and Cambridge 2 each. From whooping-cough Philadelphia 4, New York, Chicago and Pittsburgh 2 each, Cincinnati, Cleveland and Tannont 1 each. From erysipelas Chicago and Washington 3 each, New York 2, Baltimore, Boston and Everett 1 each.

In the thirty-three greater towns of England and Wales, with an estimated population of 10,846,971, for the week ending December 21st, the death-rate was 18.2. Deaths reported, 3,789: acute diseases of the respiratory organs (London) 302, diphtheria 86, measles 77, whooping-cough 73, scarlet fever 55, fever 39, diarrhea 26.

The death-rates ranged from 11.3 in Derby to 24.8 in Plymouth: Birmingham 21.8, Bradford 19.6, Croydon 15.0, Halifax 13.8, Hull 17.0, Leeds 17.8, Leicester 15.5, Liverpool 23.5, London 17.2, Manchester 18.5, Newcastle-on-Tyne 19.7, Nottingham 19.1, Salford 19.5, Sheffield 18.2, Sunderland 16.3.

METEOROLOGICAL RECORD

For the week ending December 26th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 26, 1896, TO DECEMBER 31, 1896.

MAJOR WILLIAM R. HALL, surgeon, relieved from duty at Whipple Barracks, Ariz., and ordered to Washington, D. C., for duty.

FIRST-LIEUT. IRVING W. RAND, assistant surgeon, relieved from duty at Fort Clark, Tex., and ordered to Fort Huachuca, Ariz., for duty.

FIRST-LIEUT. ALEXANDER S. PORTER, assistant surgeon, relieved from duty at Fort Huachuca, and ordered to Whipple Barracks, Ariz.

The leave of absence on surgeon's certificate of disability granted MAJOR WILLIAM C. SHANNON, surgeon, is extended three months on surgeon's certificate of disability. Fort Custer, Mon.

The leave of absence granted CAPTAIN WILLIAM L. KNEEDLER, assistant surgeon, for seven days, San Diego Barracks, Cal., is extended twenty-three days.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE TWO WEEKS ENDING JANUARY 2, 1897.

R. M. KENNEDY, passed assistant surgeon, ordered to the Naval Hospital, Norfolk, December 28th.

CHARLES T. HIBBETT, surgeon, ordered to the Norfolk Navy Yard.

N. MCP. FERELEE, surgeon, detached from the Norfolk Navy Yard and ordered to hold himself in readiness for sea.

R. WHITING, surgeon, detached from the "St. Mary's" and ordered before the retiring board at Washington, December 28th, then placed on waiting orders.

R. P. CRANDALL, passed assistant surgeon, detached from the Naval Hospital, New York and ordered to the "St. Mary's."

L. MORRIS, assistant surgeon, ordered to the "Essex."

A. R. WENTWORTH, passed assistant surgeon, detached from Naval Hospital, Portsmouth, N. H., on relief and ordered to the "Marblehead."

E. H. GREEN, surgeon, detached from the "Marblehead," on reporting of relief and ordered to Naval Dispensary at Washington, D. C.

H. B. FITTS, passed assistant surgeon, ordered to Naval Hospital, Portsmouth, N. H.

A. C. H. RUSSELL, surgeon, detached from the Naval Medical Examining Board, New York, on relief and hold himself in readiness for the "Lancaster."

J. M. EDGAR, surgeon, detached from the "Saratoga" and ordered to the "Vermont."

H. WELLS, surgeon, detached from the "Vermont," on relief and ordered as member of Naval Examining Board, New York.

W. C. BRAISTED, passed assistant surgeon, detached from the "Columbia" and ordered to the Naval Hospital, Newport, R. I.

SOCIETY NOTICE.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—The annual meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, January 11th, at 8 o'clock.

Dr. A. T. Cabot will read a paper entitled: "Cyst of the Brain—Epilepsy." Discussion by Drs. J. J. Putnam and M. H. Richardson.

Dr. H. A. Lothrop will read a paper entitled: "A Case of Hypospiad." Discussion by Drs. A. T. Cabot and M. H. Richardson.

JAMES G. MUMFORD, M.D., Secretary, 197 Beacon St.

RECENT DEATHS.

BYRON W. MUNSON, M.D., died at Sharon, Conn., January 2d, aged fifty-three years. He served through the late war in the medical department, and for about ten years was superintendent at the State Soldiers' Home at Noroton.

DANIEL MARCH, JR., M.D., M.M.S.S., of Winchester, died in Woburn, January 1, 1897, aged fifty-two years, of angina pectoris. Dr. March was born in New Haven, Conn., but came to Woburn with his parents when a boy. He graduated from the medical school of the University of Pennsylvania in 1868. After serving as house physician of the Episcopal Hospital in Philadelphia for over a year, he removed to Pittsburgh, where he practised for a time. He came to Winchester in 1879, and had a large practice in that town and vicinity. He succeeded Dr. Winsor, of Winchester, as medical examiner of the fourth Middlesex District about ten years ago and had held the office ever since. He fell over a wire fence a few days ago while crossing a lot and received a severe shock, from which he had suffered considerably, and he had thought of going away for a while to recuperate. He was a member of the East Middlesex Medical Society, the Calmet Club of Winchester and other societies. He was married to Miss Jennie S. Stevenson of Pittsburgh, who survives him.

BOOKS AND PAMPHLETS RECEIVED.

Solutions Dobell. Anterior Soft Hypertrophies of the Nasal Septum. By Edwin Pyncheon, M.D., Chicago, Ill. Reprints. 1896.

Fourteenth Annual Report of the Trustees of the Soldiers' Home in Massachusetts, at Chelsea, for the year ending June 30, 1896.

A Series of Articles on Speech-Defects as Localizing Symptoms, from a Study of Six Cases of Aphasia. By J. T. Eskridge, M.D., Denver, Col. Reprint. 1896.

On Movements of the Eyelids Associated with Movements of the Jaws and with Lateral Movements of the Eyeballs. By Harry Friedenwald, A.B., M.D. Reprint. 1896.

Ueber den Werth der Vasogenpräparate (Pearson). Von Dr. Goliner in Erfurt. Separat-Abdruck aus Reichs-Medicinal-Anzeiger, No. 23, Jahrgang, 1896. Verlag des Reichs-Medicinal-Anzeigers, B. Koenig, Leipzig.

Transactions of the American Gynecological Society, Vol. XXI, for the Year 1896. Philadelphia: Wm. J. Dornan. 1896.

The Surgical Treatment of Intracranial Tumors. By William W. Keen, M.D., Philadelphia. Reprint. 1896.

Original Articles.

THE TREATMENT OF FLAT-FOOT.¹

BY J. S. STONE, M.D., BOSTON.

In a normal foot lines drawn downward along the middle of the leg should pass through the second toe in front and the middle of the heel behind, while a line drawn backward through the great toe should pass through the middle of the heel. As seen from above, the inner border of the foot should be slightly concave and nearly parallel with the inner border of the opposite foot. The normal range of voluntary motion with the knee held straight should be from one hundred and thirty or forty degrees in plantar flexion to a dorsal flexion ten or twenty degrees beyond a right angle, while there should be about thirty degrees each in abduction and adduction.

The distribution of the weight may be excellently studied by looking up through plate-glass on which the foot rests, a method first used in the study of flat-foot

Improper shoes and improper attitudes, the latter in part dependent on the former, play a most important part in the causation of nearly all these cases. The delicate feet of children, which are arched from birth, are put into shoes with narrow toes and a convex inner border,—a custom which is continued through life. And as if to add insult to injury children are taught to toe out.

Thus the fore-foot is abducted while the great toe is further forced into the valgus position. Owing to the direction of the tarsal joints abduction of the fore foot is inseparably associated with eversion and with a rotation of the bones on an antero-posterior axis. The term "pronation" is applied by Lovett to this combined movement of abduction, eversion and rotation.² The position of pronation is the position of weakness.

In order to determine the relative influence of the various muscles in maintaining the arch, the effect of pronation, and the effect of tonic contraction of those muscles which tend to pronate the foot, some experi-

The figures represent the pull in pounds on each tendon separately, necessary to cause a beginning change in the shape of the foot. When in normal position this pull raised the arch a little. When pronated it took the strain off the ligaments.	Bearing a weight of 60 pounds.		Bearing a weight of 120 pounds.		Bearing a weight of 60 pounds, with the foot in a pronated position.

by Dr. Lovett. While an imprint on smoked paper gives merely a composite picture of all the positions which the foot has assumed, the view through the glass shows not only the contact line at any moment but shows the weight-bearing surfaces as white anemic areas. With a foot in normal position most of the weight is borne by the middle of the heel and the middle of the ball of the foot, beneath the heads of the second, third and fourth metatarsals. The great toe seems not so much to bear weight as by a constant balancing to throw the weight off itself toward the outer portion of the foot.

The outer, slightly arched side of the foot is relatively strong. The inner side, owing to its high arch, is relatively weak. When, however, the two feet are viewed together the longitudinal and transverse arches form a dome the circumference of which is in contact with the ground.² Elasticity and strength are thus secured so long as the muscles give proper support.

Aside from those cases of flat-foot due to congenital deformity, rickets, paralysis and trauma, the ordinary "static" form due to a disproportion between the muscular strength and the demands made on the foot, measured both in time and in weight, may develop at any time under unusual strain, but is particularly apt to begin in early childhood or in adolescence.

ments were tried with the normal amputated foot of a man of middle age.

The tibia and fibula were fastened securely to a vertical bar upon which a known weight could be placed. The tendons of all the muscles of the leg were then isolated at a point just above the ankle, their relations beneath the annular ligaments being left undisturbed. To each tendon a wire was fastened, so that by means of a spring balance a definite pull could be put upon any tendon.

The results are shown in tabular form.

The last three columns represent the pull necessary to bring about a change in the arch when the muscles are opposed by a steady traction on the pronei and the tendo-Achillis.

It was found that when two or three tendons, as for instance the tibialis anticus, tibialis posticus, and flexor longus pollicis were pulled upon simultaneously, the total traction necessary to cause a beginning change in the arch approximately equalled the traction on any one tendon necessary to cause a similar change.

That the distribution of the weight-bearing surfaces⁴ might be carefully studied, a series of photographs was taken of the same foot as it rested upon glass vertically over the camera. Careful measurements of these photographs show a lengthening of the foot, as

¹ An abstract of which was read at the Annual Meeting of the Massachusetts Medical Society, June, 1896.

⁴ See article on the Foot, Reference Handbook of the Medical Sciences.

measured from the tip of the heel to the tip of the great toe, of four per cent. under a pressure of eighty pounds. This increase in length is diminished to three per cent. by traction of twenty pounds on any tendon. Traction on either the flexor or extensor of the great toe or on the tendo-Achillis muscles, which affect the limits of the measurements taken, decrease the length a little more.

The breadth of the surface of the heel in contact with the glass is increased about four per cent. under a pressure of eighty pounds; an increase which disappears with traction of twenty pounds on any ten-

don. A traction of forty pounds on the tendo-Achillis diminishes this measurement by about four per cent.

The breadth of the fore-foot across the heads of the metatarsals increases nearly three per cent. under a pressure of eighty pounds. This increase is counteracted by a traction of twenty pounds on either the extensor longus digitorum or the peroneus longus, the latter muscle playing an important part in maintaining the transverse arch.

The instantaneous photographs, one set of a normal foot, the other of a markedly flattened and pronated foot, show the behavior of the transverse and longi-

1. Normal position. Under no weight. All muscles relaxed.

2. All muscles relaxed. Foot pronated.

3. Tibialis anticus.

4. Tibialis posticus.

The difference between (1) the foot at rest in a normal position, and (2) the relaxed and pronated foot under a weight of eighty pounds is most marked in the contour of the inner side of the foot. With the foot still under the same weight, traction of twenty pounds on the (3) tibialis anticus or (4) tibialis posticus tends to restore the normal outline of the inner side of the foot, and also to throw the anterior weight-bearing surface to the outer side.

5. Peroneus longus.

6. Peroneus brevis.

7. Peroneus tertius.

8. Extensor longus digitorum.

In each of these photographs the foot is under a weight of eighty pounds, pronated and relaxed, except for a traction of twenty pounds on the tendon indicated. In each the outer border of the fore-foot is raised, the outer portion of the longitudinal arch is heightened, the axis of the weight-bearing surface of the heel is directed toward the great toe, and the convexity of the inner border seen in (2) the relaxed and pronated foot is not in the least decreased. In short the peronei and the extensor longus digitorum are active pronators.

tudinal arches under muscular activity in walking. In each the longitudinal arch is considerably heightened excepting at that moment when the heel and toes are in contact with the ground. In the normal foot the transverse arch is obliterated anteriorly at the same moment. It is greatly increased however as the heel is raised. In the flat-foot the transverse arch does not appear anteriorly at any time. The most striking difference between the normal and the abnormal foot is seen when the muscles are powerfully contracted in raising the heel from the ground. In the former there is a strong adduction of the fore-foot; in the

latter there is a marked increase in the pronation, already great.

From the tables given above the following deductions may be drawn: First, the muscular pull required to remove the strain from the ligaments in the pronated foot is approximately double that necessary to maintain the foot in normal position. Second, the muscular pull necessary to remove the strain from the ligament varies approximately directly with the weight borne. Third, a tonic contraction of the peroneus longus or brevis offers as much resistance to the muscles most active in maintaining the arch as a much

9. Extensor proprius pollicis.

10. Flexor longus pollicis.

11. Flexor longus digitorum.

12. Tendo-Achillis.

As in the last group the foot is under a weight of eighty pounds, pronated and relaxed, except for a traction of twenty pounds on the tendon indicated. In the last (12) photograph, however, the traction on the tendo-Achillis is forty pounds. In no case is the contour of the inner side of the foot altered from that seen in (2) the relaxed and pronated foot. The distribution of the weight on the fore-foot is not altered from the normal, the axis of the weight-bearing surface of the heel is not directed inward toward the great toe and the outer portion of the arch, although heightened slightly by the flexors (10, 11) is not raised to the same extent as by the peronei (5, 6, 7) and the extensor longus digitorum (8).

13.

14.

15.

These instantaneous photographs of the outer side of a normal walking foot (13, 14, 15) show the increase in the longitudinal arch as the foot falls and as it rises. During the period in which the heel and the toes are both in contact with the ground the whole outer border also touches.

The photographs of the bottom of the same foot (16, 17, 18, 19) show no marked difference between the foot at rest bearing half the body weight (16) and the foot bearing the whole weight at that instant in walking when the whole outer border is in contact with the ground (17). As the heel rises, however, the breadth of the foot measured across the ball, narrows about ten per cent. (18, 19). At the same time the fore-foot is adducted (compare the inner and outer borders of 16 and 17 with 18 and 19), the transverse arch, which is obliterated anteriorly in the foot while standing (16) and in the walking foot when the heel and toes are both on the ground (17), becomes more and more pronounced as the heel rises (18, 19), and the inner longitudinal or main arch is heightened, while the inner malleolus becomes less prominent.

The instantaneous photographs of a much flattened and pronated foot, painful only after long walking and then but moderately so, show certain marked differences from the normal foot. In the foot at rest bearing half the body weight (20) and in the walking foot when the heel and toes are both in contact with the ground (21) there is no trace of a longitudinal or transverse arch. As the heel rises (22, 23) the fore-foot narrows about five per cent., a half as much as in the normal foot, the longitudinal arch appears, but the transverse arch does not. Where the transverse arch should appear there is a large callus. Instead of an adduction of the fore-foot as is normal (18, 19), there is an increase in the abnormal abduction (compare the outer and inner borders of 22 and 23 with 20 and 21, and with 18 and 19) and a marked increase in the abnormal prominence of the internal malleolus. It is remarkable that with all this pronation there is not a hallux valgus.

stronger tonic contraction of the tendo-Achillis. This opposes the view that contraction of the tendo-Achillis plays a very important part in the etiology of flat-foot, but confirms the importance of securing perfectly free mobility, particularly in adduction, in the treatment of flat-foot.

These facts show the importance of an increase in weight and the assumption of the weak, pronated attitude in the causation of flat foot. The muscles thus handicapped become exhausted and allow the astragalus, through which the entire weight of the body is transmitted, to drop downward, forward and inward, from its support on the os calcis, which is in turn lowered anteriorly and at the same time rotated on its long axis in such a manner that the weight-bearing surface is shifted inward. The changes in the positions of the other bones are, in short, those of abduction

onto the great toe and the first metatarsal. The middle of the heel and the middle of the sole lose their function owing to the fact that the eversion of the foot has brought them outside the lines of weight transmission, drawn down through the middle of the leg. The arch flattens. The characteristic deformity and awkward shuffling gait come on.

As regards treatment those cases of simple pronation, the "weak foot" of Whitman, are to be distinguished from those in which there is in addition a breaking down of the arch, while the latter class must be subdivided into those which permit the normal range of mobility and those which are rigid.

In the milder class of cases, as Whitman points out,⁵ attention must be given first to teaching a correct attitude. Those required to stand should be taught to throw the weight as much as possible on the outer

16.

23.

tion and rotation secondary to the change in the position of the astragalus.

The abnormal strain put upon the ligaments is most marked in those supporting the head of the astragalus and in the calcaneo-astragaloid interosseous. As these yield, they give rise to the characteristic pain and tenderness about the head of the astragalus. The abnormal distribution of pressure and the yielding of other ligaments may give rise to symptoms in other parts of the foot. Pains in the calf are usually due to muscular strain, while those in the knee or hip may be explained by the rotation of the whole limb due to the impossibility of any rotation of the astragalus between the two malleoli. Congestion, muscular spasm, and later muscular contracture and inflammatory adhesions follow.

The weight is shifted inward onto the weak side of the foot. An abnormal amount of work is thrown

side of the foot, to avoid toeing out, and to utilize the long flexors by feeling the ground with the toes, rather than to allow the weight to fall passively on the heels. The muscles should be rested by a frequent change of attitude.

The great disadvantage under which the muscles labor in pronation has already been shown. Proper shoes are of the utmost importance in the prevention of pronation. A good shoe⁶—and such is now sold by many dealers—should have a straight inner border, a low, broad heel, and a high shank not cut away too much on the inner side. The forward part of the shoe should be at a slight angle with the heel, that the fore-foot may be held adducted. The breadth across the heads of the metatarsals should be that of the foot

⁵ Whitman: A Study of the Weak Foot, Transactions American Orthopedic Association, vol. viii, 1896.

⁶ Lovett: The Mechanics and Treatment of the Broken-down Foot, New York Medical Journal, June 20, 1896.

bearing half the body weight. It has been shown above that the breadth of the foot in walking is never greater than this, that in fact the foot becomes narrowed as the heel is raised from the ground. The difference in breadth between the foot bearing no weight and that bearing the full body weight is about ten per cent. Considerably more than half of this increase in breadth occurs when the foot bears half the body weight. The difference in breadth between the foot bearing the whole weight and that bearing half the weight is thus but slight.

If with such shoes there is still a tendency to pronation, it may be overcome by building up about a quarter of an inch the inner side of the heel and sole, opposing the eversion in this way. This measure is particularly applicable with children.

Next in importance to placing the muscles at a mechanical advantage, come measures directed to increasing the muscular strength. Bathing, rubbing and exercise are necessary, together with any proper constitutional treatment. Certain exercises are of particular value, and should be practised at frequent intervals for a few moments at a time. Springing onto the toes and at the same time separating the heels, walking on tip-toe, and adducting the foot against resistance are among the simplest and most efficient exercises. Bicycle riding is a most useful exercise, strengthening the muscles which support the arch while placing but little weight upon it.

In those cases in which the arch has yielded, or is yielding, these milder measures are often not sufficient. Some form of mechanical support is then necessary. Padding of saddler's felt is useful temporarily, while a pad sewed to a leather insole is rather more permanent. Any form of support, however, which presses upon the shank and inner side of the shoe is not satisfactory for any length of time.

Among the more permanent supports nothing has yet proved so generally satisfactory as the metal plate, either of steel or bronze, accurately fitted to the shape of the foot in a corrected position. The pattern of Whitman,⁷ or that described by Lovett,⁸ are in common use. The latter pattern is certainly better adapted for use in those cases of anterior metatarsalgia due to a lowering of the transverse arch, and frequently entirely relieved by raising the plate anteriorly, immediately behind the heads of the metatarsals to which the pain is referred. Whatever pattern is adopted, the plate must fit with accuracy. Where possible it should be fitted at the workshop. Otherwise it is best made on a plaster-of-Paris cast run in a mould made by placing the greased foot lightly in soft plaster. A plate which causes pain is not satisfactory, and any chafing or reddening or cutting of the skin is to be remedied at once by a change in shape. Bony prominences and sensitive points are not indicated in a cast. Recurrence of the old pain after a plate has been worn several weeks is probably due usually to an increase in the height of the arch, brought about by the advantageous position in which the muscles work. In such cases relief follows slight raising of the plate, in order to give the arch its accustomed support.

Limitation of motion, as seen in the rigid type of flat-foot, may be due to muscular spasm, muscular con-

traction, or inflammatory adhesions. From whatever cause arising, it must be overcome. Simple muscular spasm usually ceases as the pain and sensitiveness subside under the ordinary methods of treatment. Muscular contracture, however, requires systematic stretching. Contraction of the tendo-Achillis may be overcome by manipulation and exercises which dorsiflex the foot when the knee is fully extended. A limitation of adduction has been shown to be more important than a limitation of dorsal flexion. It must also be overcome by persistent exercise and manipulation. The Shaffer shoe is not usually within the reach of the general practitioner.

In cases in which inflammatory adhesions have formed, two courses are open. The most prompt and satisfactory method is to etherize the patient, break up the adhesions fully, and hold the foot at rest in plaster for several weeks in an over-corrected position. A foot thus treated always requires a supporting plate before any weight whatever is borne upon it.

When circumstances make this radical treatment impossible, the resistance of the adhesions may be gradually overcome by manipulation and exercise, combined with a gradual building up of the inner side of the shoe, and of the arch by means of pads or plates gradually raised. In such cases treatment should not cease until the full range of normal mobility has been attained.

As in the causation of flat-foot muscular inefficiency, either absolute or relative, is the most important factor, so any treatment which is satisfactory must aim principally to strengthen the muscles. In helping the muscles to regain their tone plates are very efficient. Any treatment, however, which makes necessary the permanent use of plates or other form of support is in so far inefficient and unsatisfactory. The aim should always be to restore the normal muscular support.

In conclusion, I wish to acknowledge my indebtedness to the works of Lovett, Whitman, Bradford and Dane, and to thank Dr. S. W. Ellsworth for kind assistance.

MENTAL AUTOMATISM IN EPILEPSY: A PSYCHOLOGICAL STUDY.

BY L. PIERCE CLARK, M.D.,

First Assistant Physician at Craig Colony, Sonoma, N. Y.; Member of New York Neurological Society, etc.

THE presence of mental automatism in epilepsy and kindred disorders of reduction in consciousness is common and frequent, and is thereby rendered a subject of great interest for close investigation by the neurologist, psychologist, alienist and medico-legal expert. Its very frequency and the protean forms in which it manifests itself necessitates careful study in order to estimate the degree of responsibility of the individual as a volitional agent. That automatism which manifests itself in epilepsy is intimately associated or dependent upon the disorder of consciousness is an hypothesis which has long since been ably defended by various writers, and especially by Hughlings Jackson in his well-known writings upon epilepsy.

It is still a matter susceptible of two different interpretations as to just what this disorder of consciousness may be: first, that in the presence of mental

⁷ Study of the Weak Foot.

⁸ Lovett and Dane: Affections of the Arch of the Foot commonly classified as Flat-foot, New York Medical Journal, March 7, 1896.

automatism, no consciousness exists; second, that during the automatic state consciousness exists, but in such an attenuated and disordinated form as to be incapable of registering acts with any degree of permanency — thus a temporary or permanent amnesia of the automatic acts persists on the return to normal consciousness. If the presence or absence of amnesia is to be a test whether or not consciousness exists in the automatism, we are forced to accept both theories as an explanation in order that we may cover all phenomena. It is comparatively easy to see how these two theories would blend and give us an explanation of all the various motor and psychical phenomena present in this interesting condition of epilepsy.

Certain epileptics have an accurate knowledge of their acts which were performed while subject to automatism; others have no recollection of the occurrence of such acts, although it must be said that the majority of this latter class are open to suggestion and quickly incorporate any facts which may be told them of their previous disordered state of consciousness. Whether these epileptics are particularly open to hypnotic suggestion because of their peculiar mental make-up, which may have given origin to their epilepsy and its sequent mental automatism, or, whether a detailed statement of their former acts served to revivify the but faintly impressed images received while consciousness was in a disordered state, are both questions which it would be of great interest to ascertain by future study.

It is worthy of remark, that the acute mental disturbance caused by and found in epilepsy partakes more of the nature of mental automatism accompanied by acute delirium than any other form of insanity.

These periods of automatism usually follow convulsive seizures in epilepsy; so it is essential that we should examine these attacks and ascertain, if possible, their nature and influence upon this disordered state. That the condition generally follows *petit mal* rather than *grand mal* is a matter of record, although the cases which will be presented in this article were all of *grand-mal* type and in only one case, after a single attack of *petit mal*, did automatism ensue.

The question naturally arises, Why should this condition be a more frequent sequela to an epileptic seizure than to all other disorders of consciousness, which occur in other pathological conditions? While recognizing that the essential basic constituent of an epileptic attack is a disorder in consciousness, which may or may not be associated with a convulsion, yet the structural change in the so-called substratum of consciousness which underlies this disorder must be carefully investigated in order to obtain an accurate conception of the relationship. It is undoubtedly proven that the sum total of nervous action is essential to the correct concept of consciousness. This being the case, any great disorder in the cerebral activity must necessarily influence the complex state or better states of consciousness.

Todd, Robertson, Jackson and Gowers have shown how sudden, excessive and persistent nervous discharge of one or all of the cortical brain centres may be followed by temporary paralysis which may be either local or general; local, if the cortical exhaustion of inhibition were local, and general, if the disturbance of the cortex were general or diffuse. While we do not contend that consciousness has such a materialistic basis, which to be true would be ideal, yet it

is probable that an analogous condition obtains in all such reductions and attenuations in subject-consciousness, such as mental automatism appears to be. The character and degree of mental disturbance attending the epilepsy is probably the greatest factor in deciding the absence or presence of automatism in any single case. The cases which have recently come under observation have all been those more or less addicted to the use of alcoholic stimulants, and present a fairly distinct and uniform mental type. They are all nervous and excitable, and subject to periods of extreme irritability which is most noticeable in the inter-paroxysmal state.

Notwithstanding the automatic acts performed in the post-convulsive state are usually described as of a simple character, yet the relative simplicity of such mechanical acts is determined by the degree of intelligence of the subject, as well as the character of the seizures and their severity in the higher realms of mental activity. While one may perform such simple acts as to walk about assuming a studied and anxious expression of countenance, another more intelligent and in whom a like mental disturbance has taken place, may perform such complex acts as to write letters to his friends which are very well expressed (as Case III). Again (as Case II), he may perform difficult arithmetical problems. These last-named acts are undoubtedly of a high intellectual order, and seem to prove that the change in consciousness in all cases was not of a horizontal reduction, but certain areas of the brain remain as foci undisturbed and are still capable of giving direction to intelligent thought and action.

The ordinary manifestations of automatism may be easily diagnosed. To the careful observer the patient may be seen performing a number of contending, purposeless acts, in which there is marked incoherence in words, sentences and continuity of thought. His association of ideas is broken. His remarks pour forth in a disjointed, fragmentary mass, and no special idea remains long enough to make its impress upon consciousness and so remain fixed and permanent in the normal state. All power of inhibiting ideas which do not follow the laws of association is completely lost, and attention is attenuated to a marked degree. There is no tendency toward a unity of consciousness, which is imperatively necessary for the existence of attention. While the foregoing description holds for the typical case, there are many more atypical conditions which are extremely difficult to understand and recognize.

When we compare the two disordered states of consciousness, somnambulism and automatism, we recognize that they are antipodal states and cannot exist at the same time, but may be found in the same case at different times. It is as common to see a case of somnambulism perform relatively complex acts while in the disordered state, as it is rare to observe the same degree of complex acts performed in automatism. But that they have some association is well proven by the fact that a great number of epileptics who are afflicted with mental automatism have been, in earlier life, somnambulists. In Case I given here, this state of somnambulism still persists in a mild form; and at these times, when he is apparently automatic without any seizure having preceded it, he is doubtless somnambulant. In short, while somnambulism might properly be defined as a tendency towards a unity of consciousness in which the subject is possessed of a fixed

idea which he endeavors to accomplish or realize, automatism, on the other hand, may be described as the condition in which many states of consciousness have equal tendencies to present themselves at the same time, and the inhibition of higher centres, such as the will may call into action, are withdrawn or lost. There are varying degrees of the disordered state of consciousness, ranging all the way from the performance of simple physical acts to those of very complex mental ones. Therefore, the milder forms of automatism may approximate a unity of consciousness, and in this way resemble or shade off into true somnambulism.

The writer will present several cases of automatism which have come under his observation very recently.

CASE I. Male, thirty-eight years of age, a merchant by occupation. His epilepsy has been in existence for three years. The assigned cause was alcoholism. A maternal grandmother had epilepsy, and patient's father died of "brain fever." The majority of his attacks are of the *grand-mal* type and occur about once a week, generally at night or in the early morning hours. His attacks have never been preceded by an aura. He had three slight attacks of mental automatism prior to his admission to Craig Colony. One was of a somnambulant character; while in this state, he left the house in a partially disrobed condition and walked about the grounds for ten minutes, apparently in search of something, but as he did not find it, he returned to the house, and remained in a sound sleep for six hours. At other times, during attacks of epileptic automatism, patient walks about and does various purposive acts, such as cleaning the lavatories and making beds. During these times, if he is at all molested, he is liable to be very irritable and pugnacious. There is a general muscular rigidity attending all purposive acts, and these are performed more rapidly than normal movements in every-day action. He rarely converses with any one at these times, unless he is spoken to, and then his replies are intelligent and direct. During one of the attacks he carried a patient, who slept in an adjoining bed, about the room and acted foolishly and simple. Following these periods of sleep-walk, which last from fifteen minutes to two or three hours, he generally returns to his bed and sleeps soundly. He has no knowledge of these attacks the next morning, and would not know that they had taken place were it not for a slight feeling of "weariness." Occasionally during the day following a regular attack of epilepsy, he will perform for a few moments these same automatic movements; but if left alone and made to lie down, he quickly recovers from them without doing any personal violence. Whenever opposition has been made to his performing work which he desired to do while in this disordered state, he has shown great personal violence. An illustration of this is given in the following:

After a seizure which occurred while patient was coming to the colony, he assaulted two brakemen and smashed a car window and a seat as a result of a brakeman's interference when he attempted to raise the car window. He had had a slight epileptic attack a few minutes before, and was automatic. He is very strong and muscular, but displays more strength during these periods of automatism than in normal muscular action. He is clear mentally, and quite capable of performing good labor, if not interfered

with and made to do differently than he does in this abnormal cycle which rehabilitates normal consciousness. After one of his recent attacks, the patient sat up in bed and stared about him in a bewildered manner; he arose quickly and began to run about the house performing all sorts of automatic acts such as searching for imaginary objects under the beds, in the attic and lavatories. Occasionally, he has had periods of sleep-walk without having had a seizure; he is likewise unconscious in the morning of having had such an attack. This last-mentioned phenomena is especially noticeable when he has not received his regular dose of sleeping medicine at night.

CASE II. Male, thirty-two years of age, a printer by occupation. Epilepsy has been existent for thirteen years. Cause was unknown. No neurotic family history was obtainable. General character of attacks is *grand mal*. His attacks are generally nocturnal, occurring in the early morning hours, and they are not preceded by an aura. At the time of admission, patient presented some of the typical mental characteristics of the epileptic, the most noticeable being his extreme irritability and amnesia which preceded and followed his attacks. He was unable to carry on prolonged or sustained mental labor. The patient was placed upon Flechsig treatment, and for three months after he had no attacks; the morning after this period of immunity he had a severe convulsion. He arose, dressed himself immediately after the attack, and conversed in a rational and intelligent manner with those about him. After breakfast, he was absent from the house for an hour or so, during which time it was afterward learned that he visited the shop where he was accustomed to work, but what he did there is not positively known. He returned to the house, lay down, and soon fell asleep, and remained asleep for three hours. On awaking he was perfectly oblivious of what had occurred, and was very much surprised to find that it was morning, that he was dressed and had apparently been out to work. He had no recollection of what he had done during this interim, and persistent effort to recall what had happened was also unsuccessful. In describing this occurrence, which is altogether unexplainable to the patient, he uses the expression, "I must have done so and so." The attack preceding this period of automatism was of the typical *grand-mal* character; general muscular convulsion of clonic spasm lasting for two minutes ensued. Heretofore the patient has always had a prolonged sleep-stage following his regular attacks. This time the sleep-stage did not follow, and had the automatism not followed the attack, the seizure would not have been especially noteworthy.

CASE III. Male, thirty-one years of age, a clerk by occupation. Cause of his epilepsy is unknown. No neurotic history. Patient's attacks are of *grand-mal* type, and occur every two or three weeks, both by day and by night, generally in the early morning hours. Preceding his convulsive seizures there is a tonic spasm of the forearm and arm of the right side. When this is especially severe, the extensors of the forearm are sufficiently active to cause the patient to drop whatever he may be holding at the time. This is generally attended by slight inspiratory movement, causing a quick closure of the epiglottis. Patient is entirely unconscious of the significance of this muscular movement, which may last two or three hours before the general convulsion takes place. After one

of his severe attacks had occurred and the sleep-stage had been omitted, the patient engaged in his daily work, which was to care for one of the offices and act as messenger. There was but little change noticeable in the patient, except that he seemed to be slightly incapable of understanding any question addressed to him. He performed his duties with alacrity, and during the day carried messages about the colony and distributed packages as he was ordered. He conversed upon almost any subject suggested, and did so in a rational manner; yet there was an unnatural appearance about the eyes and facial expression which at once, to the careful observer, would indicate that he was not in a rational state. During the day he made but one mistake in carrying messages and packages. The same day he received some papers and letters from his friends; the following morning he was entirely oblivious of their receipt and of all the other occurrences of the previous day.

In another case, the period of automatism makes its appearance without a convulsion having taken place, although what might be termed a very slight attack of *petit mal* may supervene. The patient will whistle and sing odd bits of song, and at the same time almost falls upon his hands and knees, but quickly recovers himself and runs about the house, laughing boisterously and doing various foolish acts suggestive of a mild state of intoxication. After such attacks the patient has no recollection of anything that has occurred during the fit and the automatic state following.

In all cases a family history of somnambulism was obtainable, and in all cases which have come to the attention of the writer no aura was found to precede the attacks. It seems probable that the so-called psychical attacks of epilepsy are really periods of automatism.

In one case, the patient, while in one of the mild forms of *petit mal*, would converse with any one, but, as she afterwards stated, she was hardly conscious of what she said and did at those times, and was very apt to express ideas antithetical to those which she really entertained, both at the time and previous to the attack. Such attacks last for two or three minutes; and in the normal consciousness which immediately follows, the patient remembers what she has said during the period of automatism, and often makes an effort to correct the wrong ideas which were expressed.

In a case which has recently come under the writer's observation, a description of the mental automatism is as follows: The first attack occurred about five years ago, and followed a severe convulsion. The patient was taken to the police station and placed in restraint for two days, then he was removed to the hospital and placed in restraint for six weeks. During this time he was incoherent, and showed considerable violence in his manner, but did not attempt any assault. The return to normal consciousness was sudden and absolute. Three years after this first attack, while on his way home from work as railroad engineer, he stopped in a way station, threw out both operators, and sent a message by telegraph to the central station and received the reply. After having done so, he locked the door of the station and proceeded on his way home. He only became aware of what he had done by the fact that he found the key of the station in his pocket the next morning. The

messages were carefully sent and received during this attack of automatism. He himself was somewhat surprised that he was able to send a message with so few mistakes. Upon return to normal consciousness, which is always sudden, patient is unable to recall any of his past acts performed while in the automatic state.

To show the length of time that automatism may be present after an attack of epilepsy the following case is presented: M. B., female. She had a severe attack the night before admission to Craig Colony. After three weeks of automatism patient became conscious of where she was, and partially conscious of what had occurred since her admission to the colony. It was extremely difficult at the time of her admission to tell whether this case was in the automatic state, or whether she was suffering from a certain degree of mental impairment as a consequence of her epilepsy, although it is now obvious that the former condition was her true state, as evidenced by her return to normal consciousness and her performing daily work in an acceptable manner.

Slight attacks of epileptic automatism occur frequently, but they are diagnosed with difficulty, and occasionally disappear before one can say positively that they have really been present. The ability to decide the degree of responsibility in such epileptics becomes extremely difficult.

The close relationship which all disorders of consciousness sustain to one another, especially when automatism is present, is manifest when such conditions are studied closely. Somnambulism was present in Case III from early life, and the habit was also found in his family history long before his epilepsy began.

Just what mental condition predisposes one case of epilepsy to mental automatism more than another, it is impossible at present to state. However, it is probable that certain subjects would not suffer from mental automatism if they did not have epilepsy or some other disease which materially interferes with cerebral activity, resulting in marked disturbance or reduction in subject-consciousness.

REMARKS ON MATERNAL IMPRESSIONS.¹

BY W. T. COUNCILMAN, M.D., BOSTON.

I SHALL not confine myself strictly to the subject of maternal impressions, but shall make some general remarks on the subject of malformations and the theories concerning their causes.

By malformations is understood a marked departure in structure from the type of the species. There is no sharp line of separation between malformations and the slight departures from the normal type which are known as variations, and which when advantageous for the species may be continued and rendered permanent by natural selection. The most pronounced malformations in which there is an extreme departure from the normal type are known as monstrosities.

The beginning of our knowledge of malformations really dates from the foundation of embryology by Wolff in 1759. Previous to this time they had more of theological than scientific interest. The principal question regarding them was whether they were pre-

¹ Remarks before the Obstetrical Society of Boston, November 17, 1896.

formed or whether they were due to secondary causes modifying the original direction of growth. Swammerdam attributed their formation to a modification of the germ produced at the time of fecundation. Such an idea was a necessary consequence of the doctrine of the pre-existence of germs. If it was admitted that monstrosities existed pre-formed in the germ, it followed that God must create them as such. Malebranche refused to admit this. Regis contended that this was the case, and if normal beings showed the infinite goodness, the malformations showed the infinite power of the Creator. Duverney, in 1706, described a double monster of the type of ischiopagus, and showed that certain anatomical conditions were incompatible with the theory that the monstrosity was due to the accidental union of two fetuses. If it did not result from the fusion of two germs, it must have existed as such from the beginning, and this showed the pre-existence of monstrosities. There was a famous discussion on this question in the Academy of Sciences in Paris which lasted from 1824 to 1840, between Lemery and Winslow. Lemery showed a monstrosity with two heads and a single body, which he explained by the fusion of two embryos. Winslow combated this idea, taking the side of the pre-existence of monstrosities. The work of Wolff may be said to have been completed in 1817 by the work of Baer and Remak. The final acceptance of the theory of development overthrew the theory of the pre-existence of monstrosities. If they do not exist in the germ, they must develop from the ovum.

The first scientific classification of malformations was given by the work of Geoffroy St. Hilaire, published in 1834. He collected all the malformations which were described and depicted in various scientific treatises, and classified them. He has done for monstrosities what Linneus has done for botany and Cuvier for anatomy.

When the idea of the pre-existence of germs, which necessarily carried with it the idea of pre-existence of monstrosities, was overthrown, it was believed that they were due to abnormal conditions acting on the developing embryo which altered the course of normal development. Then came the experimental period, in which the influence of various abnormal external conditions on the developing embryo was studied, and the attempt made to find the earliest abnormal conditions of development and to follow these in successive stages to the resulting malformation.

Experiments having for their object the production of malformations began almost simultaneously with artificial incubation. More deformities were found in artificial incubation than in the natural process, and an attempt was made to find out the conditions which produced them. It was generally supposed that artificial incubation of the eggs of chicks was learned by the French in the Egyptian campaign, but before this it had been successfully followed. The elder Etienne St. Hilaire, was one of the French savants who accompanied Napoleon in his expedition to Egypt, and on his return to France he carried out artificial incubation of eggs on a larger scale than had been previously attempted. It is possible that the monstrosities which he observed in the eggs in artificial incubation may have first excited his interest in malformations, and led to his brilliant work. He studied the action of abnormal conditions on the egg, and attempted to produce malformations after the third day

of incubation. In this he was not successful, because after the third day the chick embryo is so far formed that malformations are not possible.

Pannum published in 1860 an extensive series of observations on the subject. He subjected the eggs to various conditions, the principal means which he used being the influence of greater degrees of heat and cold; and in this way he produced various monstrosities.

The most extensive work on the subject has been that of Darreste. He began his work in 1854 at Lyons, and has prosecuted it with great enthusiasm since that time. He has now a teratological laboratory in Paris which is devoted to this work. Darreste has found that almost any abnormal conditions acting on the egg in the first days of development can lead to the production of malformations. The principal means which he has employed have been shaking the eggs in a machine devised for that purpose, subjecting them to the influence of variations of temperature, varying the position of the egg, etc. He has in this way been able to produce a large number of malformations, but he has not been able to produce at will any definite malformation.

Lombardini endeavored to modify the normal course of development by subjecting the eggs during incubation to the action of electric currents, and by rotating them. He obtained in this way monstrosities; but the nature of the monstrosity was inconstant and without relation to the treatment which the eggs have undergone.

Gerlach varnished the entire egg with the exception of a restricted space corresponding to the position of the embryo, and he found that the parts beneath the varnish did not develop; and he was able to produce in the short period which the embryo lived under these conditions, various abnormalities of development. Attempts have been made to produce malformations by making an opening in the egg and acting directly on the developing embryo.

Warynski and Fol by means of the electric cautery were able to destroy certain parts of the embryo, or to retard their development while the other parts develop. The experiments of Warynski and Fol were carried out in a better manner by Gerlach, but all of the results which have come from the action of conditions acting directly on the embryo have not been encouraging.

More encouraging results have come from the attempts made to produce malformations in the eggs of invertebrates. The egg of the echinoderm seems to be especially suited for experiments of this sort. Malformations can easily be produced in these eggs, and they nearly always take the form of double monstrosities. The work of Hertwig in this respect is very interesting. He found that by subjecting the eggs to various conditions, especially to the conditions which could exercise a more or less benumbing effect on the egg, instead of one, two or more spermatozoa could enter. According to the number of spermatozoa which had entered, double or triple malformations could be produced. Other experiments have shown that double malformations can be produced in these ova in other ways.

Very extensive general conclusions have been drawn from the experiments of Hertwig. Duval assumed poly-spermism to be the general cause of double malformations, and because Hertwig produced

these by subjecting the eggs to the action of alcohol, he explains the possible fact that double malformations are more common in drunkards, by supposing that drunkenness at the time of conception might allow the entry of more than one spermatozoon. Opposed to this idea, it has been shown that poly-spermism is the normal condition in certain invertebrates. The idea of the part which poly-spermism may play in the production of double malformations goes back to the time of Jacobi in 1765, and he attributes all double malformations in man and animals in which the double being has a common stomach to poly-spermism.

Attempts have been made to produce malformations experimentally in mammals by opening the abdomen and injuring the embryos in various ways. The results of these experiments have not been fruitful. Darreeste found from his work that the most common pathological condition which he produced was abnormalities of the amnion, and this led secondarily to the formation of various malformations. There is no doubt that abnormalities of the amnion play a very important part in the production of malformations in mammalia. It has certainly been shown experimentally that malformations may be produced by the action of abnormal conditions acting on the embryo during the first days or hours of development. In man these conditions must act during the first five weeks of intra-uterine life; after that they become inoperative. The fact that certain malformations are hereditary would show that the cause of malformations may be found in some condition of the male or female cell before conjugation takes place. Cases of the heredity of certain of the minor malformations, chiefly those characterized by excess of development, such as polydactylism, are perfectly well known. The more severe types of malformations are not inherited; principally because the subjects of them are incapable of sexual life.

Of maternal impressions as a cause for malformations, it is hardly worth while to speak. There is no scientific foundation for the belief, and no proof that maternal impressions can have any effect on the developing embryo. All malformations seen in man are found in the lower mammalia, in whom the influence of impressions cannot be supposed to be of much importance; and they are also found in birds. In the case of birds, we must suppose that an impression acts on the hen during incubation and is transmitted by her to the egg which she is hatching.

There are some interesting observations as to the frequency of malformations. Peusch has found that malformations are more frequent in illegitimate than in legitimate children. This would probably speak in favor of the influence of abnormal external conditions, because the unfortunate mothers are more subject to the influence of privation and dissipation. All malformations are more frequent in females than in males. In 100,000 births, Peusch has found 454 simple malformations, 61 single monstrosities and two double monstrosities. There is a considerable difference in the species of animal in the frequency with which malformations are found. They are more common in the hog, cat and cow than they are in the horse and goat.

Malformations have been more studied, not with regard to their especial cause, but with regard to the abnormalities of development, by means of which they are produced. In this respect there is the closest relation between teratology and embryology.

Authors of treatises on malformations have been able to explain almost every malformation by certain abnormalities of the development. In general we can say that malformations are due to excess of development, to defect of development, or to the persistence of embryonic conditions. The exact steps in their formation are in most cases not known. Malformations are especially apt to occur in those parts of the body in which there is the greatest complexity in development, and in which the course of normal development is not clearly known.

His has said with regard to this, that the explanations which have been given of the malformations are to be regarded more as examples of the action of an ingenious intellect than as true explanations. The future investigation of malformations must be in the direction of embryology. The subject is more closely related to this than it is to pathology. Nothing more is to be gained from the mere anatomical description of malformations. That was practically completed by the work of St. Hilaire in 1834, and but little has been added since then.

The most interesting malformations are not those which come at full term and which strike us by their remarkable form, but those in which the development is at a very early period. Abortion is frequently due to malformations of the embryo, which lead to its death. This is especially the case in the very early abortions, which appear as retarded menstruation. The very small embryo is passed out with the hemorrhage, and is not found unless carefully searched for. Most of the questions in teratology are to be solved in the future by the study of these early embryos. Theories of their formation, founded on what embryological facts are known or supposed to be known, no matter how brilliant these theories apparently are, will be found to be as false as theories usually are.

EXCESSIVE PHYSICAL EXERCISE AS CAUSE OF NERVOUS EXHAUSTION.

BY S. G. WEBBER, M.D., BOSTON.

It is necessary to understand at the very beginning that the term "excessive" is relative and does not—indeed, cannot—mean the same for each person. That amount of exercise which can be borne by one person would be far in excess of the strength of another, and could not be endured. An Indian scout or runner could cover a distance far beyond the ability of an ordinary person; and most people can walk farther than one of my patients, who found himself so exhausted by a walk of five miles that he had to ride home.

My object is to call attention to what I believe is a source of danger at the present time, when athletics are so popular. For many, a moderate amount of exercise is as much as the pupil or patient can take with safety. Hence the need of physical examinations in every doubtful case before entering upon a course of gymnastics. The family physician should have a care in this respect over the children, and guard the weaker from harming themselves by following the fashionable tendency; for it is not merely in gymnasia that the harm is done. Fortunately in nearly all such institutions there is now at least a nominal recognition of the fact that a young man may overtax himself; and in many there is a doctor who is supposed to have

an oversight of the young men or women who attend to exercise. Yet a physician may not recognize in a hasty examination the inherent weakness which is well known to the family physician.

As now the various sports and games are in greater favor than at any time for many years past, there is need of care as to the amount of training the young receive or try to get outside the gymnasias. The fashion and rage for athletic sports, and the desire to train the body, to bring it into the highest state of discipline and under the most perfect control, is more general now: all the young men and boys—and girls, as to that—are striving to make the most of themselves physically. Baseball, football, golf, rowing, tennis, bicycling, and for the less hardy, croquet, with other outdoor games are drawing our young people into the open air as never before in the memory of this generation. The contests for which the participants prepare by a long course of training, and which attract crowds of interested spectators, have increased an hundred fold within my memory.

The influence of this tendency is felt everywhere by both sexes, by old and young. Gradually the spirit of rivalry has extended, and now the programme in athletics is nearly as long as that of former collegiate studies. There has arisen among young people a strong tendency to overdo in this direction. More good than harm comes from this popularizing of athletics. The community is gaining in that our youths are acquiring health and endurance which enables them the better to take their part in life. Now boys and young men can get in the field of sport training for muscle and eye, for brain and nerve and judgment, which formerly it was difficult to find.

There is a class of students who go into athletic training with a serious purpose, with the desire to make it an added means to the end they have in view. They have no intention of engaging in any contest of strength or skill; they recognize that they are not able to compete with their more robust fellows; but they desire to prepare themselves for more vigorous work in the study, that they may attain the best results in the class-room.

The glamour of athletic contest is thrown over them in the preparatory school and in early college life, and they come to believe that the stronger they can make their bodies, the more muscle they can develop, the more severely can they tax their brain, and the more their mental powers will develop.

Many below the average in physical stamina, who need to husband their strength carefully, begin too early to seek greater muscular power, not knowing that if they spend in the gymnasium four-fifths of their strength, they cannot use three-fifths in study.

To a certain point it is true that training the body will give vigor to the mind; but there is a limit beyond which one cannot go without the mental power, and later the physical suffering. The limit varies with each individual. And there is a limit as to the character of the training, the nature of the exercise, and also a limit as to the amount of time which should be spent in the training. It would be unwise for a boy with naturally weak legs to try at first to walk or run as far and as fast as one who was unusually robust and strong in his legs. Let him begin with light leg work, and by graduated exercise develop the muscular power, and he will be able to do a fair amount of walking, but never attain to the greater power. If he in this and

other respects cultivates immoderately the moderate power he possesses, he will do himself harm, and at length will find that he cannot use his brain in study to the best advantage. But if he will be satisfied to train his body according to the natural capacity of that body, the brain will not fail him. He may be honorable among the thirty, but cannot attain to the first three.

The fashion is now, and has been for some years, so set towards athletic sports that there is danger lest young men and boys who need to be moderate and careful in exercise should plunge into it too vigorously and suffer harm. Public sentiment is strongly in favor of a healthy mind in a healthy body, and no one raises a warning voice to restrain the young man; or if they do, the protest is too often feeble or neglected. This is true of all forms of gymnastic work. Military drill is useful to a large majority of boys, but occasionally there is one who ought not to be subjected to it. The very marked cases where it would be injurious are recognized and escape, but there are many doubtful cases, where unless such boys are carefully examined, they may suffer from the training.

It is well to keep in mind that many boys and girls, young men and maidens, need medical advice as to the amount and quality of gymnastic training which will be of greatest service to them.

No gymnastics which overtax and strain the growing youth in muscle or joints, wherein the difference in natural strength and development of individuals are not taken into account, are safe. The progress should be gradual, from light to severe, to more severe exercise until each has reached the limit of his normal capacity, and is in condition to do the best work in all departments of life. For the majority of young men and women this is far below the training needed for an intercollegiate contest of any kind.

My plea is for the family physician to study the physical and mental idiosyncrasies of his youths, not patients perhaps, and give unsought warning, if necessary, lest they run into some of the mistakes made by some of my patients, remembering that in many persons both brain and body cannot be trained to the highest efficiency. There are a few brawny blacksmiths who have a mental power proportional to their biceps, but the rule is otherwise.

The report of a few cases illustrating what I have said, will help to impress the truth of the statements made, and will show that there is some danger in the direction indicated.

Mr. H. H., age twenty-one, had been fairly well most of his life; had typhoid fever a little more than a year before I saw him. The day before he had the fever he hit his head playing football; the next day he had a severe headache, and two days later the fever. About seventeen days later he went home; and three days after, he had fever again, and was in bed five weeks. He was out of college two months and a half.

A few years before coming to college he had worked hard, and for three years had had a tremendous strain. Before the above illness he had been well, and after making up his lost time he was well. He came back in September feeling well, but about Thanksgiving time he felt dragged. After attending a football game, not playing, he felt tired; rested, and felt well till the week before Christmas. For nearly a month he worked and rested alternately, as he felt more or less tired.

He had eight hours a day college work, exercised

fifty minutes in the gymnasium, and took a gentle run afterwards. He ate well, eating a large amount of meat. He slept about eight hours and a half.

His life was regulated. He was advised to take less exercise, to be regular in his hours of study and meals, to omit some of the work he was doing. The last of May he felt well. He got through his examinations without trouble, having some headache, but not severe. He returned to college after the vacation in pretty fair condition, but somewhat tired with the sports and gayeties of the summer. He was inclined to eat rather too much meat; but he had cut down his outside work and the amount of exercise he took. He got through without further serious trouble.

The most important part of the treatment in this case was cutting down the exercise to fifteen or twenty minutes a day of less severe kind of exercise than was used at first.

This young man had practised gymnastics alone in the gymnasium. Gymnastics alone, without the association of a class, is more of a strain, less of a mental recreation, than if taken in a class. Alone, the whole time is given more fully to work, with fewer or no intermissions, and there is less variety of mental recreation.

The best results can be obtained for the average youth in class work with music. There is the exhilaration due to many taking part in the same exercises, in addition to that caused by the music. The fun and amusement turn the work and exercise into a recreation. Also in class work there is necessarily waiting one for the other, giving short periods of rest, so the gymnastics can be continued longer. In solitary work, if necessary, there should be short pauses for rest, and the time devoted to exercise should be less than in class work. I am not now speaking of those who need gymnastics as a remedial measure to overcome definite diseased conditions, but of those who being in normal health desire to increase general muscular strength and physical vigor.

Mr. M. G., age twenty-one, came to me early in 1893. He was a student. He had been ailing three or four days. He had been in another college and had broken down, doing work outside his regular college work. He then rested a year and a half. At the beginning of that break-down he had vertigo, and could not fix his mind on any subject. He entered the Sophomore Class. Two days before he came to me, he felt faint while studying; this was followed by a headache the next day, and when he came to me he had difficulty in following lectures. He complained chiefly of headache and backache; had to give up his work for about an hour. He took a sleigh-ride and felt better. When I saw him he simply could not apply his mind. He had been taking too much physical exercise, though I did not make note of how much. By moderating his work and regulating his mode of life, he succeeded in doing fairly well.

Another patient was always rather weakly and could not play like other children. When he first began to break down he felt an excessive languor. He used to take long walks to keep up his strength, often farther than his strength would warrant, and had to return home in the cars. He was finally obliged to give up study, as his mind would not work. The physical exercise was only one of the causes for this young man's running down, and probably not the chief cause.

Another patient, Mr. A., gave much attention to gymnastics in college, and played ball. He was obliged to intermit his college course, practised at the Butler health-lift, gained, and then finished college. He was always delicate and nervous, had many symptoms referable to the digestive tract, and suffered from headaches; he did fairly well for several years if he did not have too much physical strain in addition to mental. I cannot give the particulars of a long period of slowly increasing nervous exhaustion, but mention the case, as the extra physical tax in the gymnasium and in playing ball seemed to hasten a nervous collapse, which perhaps could not have been entirely prevented without a complete change in the plans of his life-work.

Another young man, J. G. M., age twenty-two, while in school, at about nineteen years of age, danced much and drilled much, being ambitious to excel in the military drill. He also played and ran in his play very much. When he left school he went into a business in which it was necessary for him to climb many stairs. The last year in school he found his mental power was not so good as it had been previously; he had to read his lessons over more frequently to understand them; it was harder to learn. After going into business and taxing his legs more, he had numbness in his legs, backache across the lower lumbar region; at times he had hot sensations, and again cold chills running down his back and legs. He was beginning to have trouble in walking on level ground.

This case is one in which there was more physical exhaustion than mental; yet the mental tire was well developed in the last year at school, and had he continued to study, no doubt it would have become still more marked.

Miss W. was a vigorous, active girl, engaged in all sorts of out-door plays and sports; was very strong, and able to do more than most of her companions, but was of delicate, nervous constitution, and did not inherit nervous vigor. She rather took pride in her good physical condition. Being much interested in the violin, she studied that instrument, practising four or five hours a day. After five years of this she broke down rather suddenly. There was excessive physical strain in addition to mental fatigue and excitement. The principal symptoms were in the legs, numbness and inability to stand, pain and tenderness in the back and head, headache and inability to concentrate her mind.

What shall we say of young children taking long walks? children eight to twelve years of age walking twelve miles on a stretch? A lady recovering from a sickness, played croquet so long that she was exhausted and her full recovery delayed. These are only examples of cases wherein exercise has been pushed beyond safe limits from a mistaken idea that thereby greater strength would be gained — not from necessity and the need of unusual exertion in life's necessary work. In each case illness and weakness was caused or hastened by the means taken to prevent its occurrence.

There are some whom we need to warn against overtaxing themselves in the very laudable design of making the most of themselves in every respect.

NOTE.—Since writing the above I have seen a young man, eighteen years old, who rode on bicycle over two hundred miles in two days. For several days he was very tired. Some weeks later he gave out mentally and physically, not having entirely recovered from the exhaustion caused by the ride.

Clinical Department.

A NOTE ON BISMUTHUM TRIBROMPHENYLICUM AS A SURGICAL ANTISEPTIC.

BY CHARLES GREENE CUMSTON, B.M.S., M.D., BOSTON,
Assistant Professor of Surgical Pathology, Faculty of Medicine,
Tufts College, etc.

It is difficult to pass an opinion regarding the real value of an antiseptic, because bacteriological experiments are not always in accord with the clinical results obtained. Such, for example, is iodoform, which theoretically is without value, while practical experience demonstrates its great virtues.

The phenols, such as carbolic acid, the chlorobromo- and iodo-phenols, cresol, pyrogallol, naphthol, etc., are the most powerful antiseptics, after those of the mineral series, but their use is limited on account of their toxic and caustic properties. These defects disappear if H O is replaced: example, phenol and salicylic acid give by their combination salol.

The reason why salol and other like products give such excellent results when applied to wounds or the mucous membranes is because they split up into their constituents in a *slow and continuous* manner, so that when a large surface is covered, the toxic and caustic action of the creosote or carbolic acid does not occur. The phenolates of bismuth easily decompose in presence of the organic liquids, and the amount of phenol liberated is sufficient to give excellent antiseptic results.

Of all the groups of antiseptics, bismuthum tribromphenylicum, or as it is also termed "xeroform," is recognized as the most active: first, because it contains, besides 49 per cent. of oxide of bismuth, 50 per cent. of tribromophenol, while other products only contain from 10 to 20 per cent. of phenol, cresol or naphthol; and, secondly, tribromophenol is more antiseptic than phenol.

Bismuthum tribromphenylicum has for chemical formula $C_6H_2Br_3O-Bi-O$, and is rapidly decomposed by acids and bases, especially when heated. But, on the contrary, it may be heated to $110^\circ C$. without decomposing and is thus superior to iodoform because it can be *sterilized*.

It is a fine, yellow, neutral powder, which does not decompose when exposed to light; its odor is slightly carbolic; it is tasteless and does not irritate the mucous membrane of the digestive tract.

Little has been written regarding the surgical applications of this product; but there is no doubt in my mind that it has a large field of usefulness in surgery. In open wounds, those in which no infection has taken place, the tribromophenol of bismuth will secure union by first intention. It appears to exercise a calming influence on burns, like iodoform. In cutaneous affections with secretion of pus, such as impetigo and sycosis, the results obtained, with this preparation were not satisfactory. In some cases of *pruritus localis sine materia* the itching was stopped by the application of this product. When applied after the curettement of tubercular abscess or glands, cicatrization was rapid.

On account of the continual development of tribromophenol and oxide of bismuth, a wound will be kept in a perfectly antiseptic condition, while the slightly irritating action of the former gives a fresh and healthy aspect to the wound.

One of the properties of iodoform is to produce granulation tissue; tribromophenolate of bismuth and other antiseptics, such as airol, euophen, iodol, etc., do not have this quality to such a degree; consequently in order to cause granulations to spring up, iodoform should be first applied, and cicatrization can be accomplished with the bismuth product. This method I tried with success in two cases of fistula in ano after having freely opened, excised and curetted the fungous masses.

My experience with the product under consideration amounts in all to twenty-six cases, as follows: five cuts of the extremities requiring from three to twelve sutures; one ulcer molle; two operations for bilateral laceration of the cervix; seven curettements for acute gonorrheal endometritis; two cases of vaginitis; three operations for tuberculosis of the bones; one abdominal hysterectomy; one tubercular abscess of neck; one sub-aponeurotic abscess of axilla, one appendicitis; and two operations for fistula in ano.

In all these cases it appeared to me that this powder gave more satisfaction than I have ever had with iodol, euophen, iodoform or tincture of iodine, all of which I have thoroughly tried. In the gynecological cases it appeared to me that this product had a marked influence on the regeneration of the epithelium.

In no case did I meet with any toxic symptoms, although in the cases of tuberculosis of the bones and tubercular abscess of the neck in a child eleven months old I applied the powder very freely in the wounds.

In closing this short note I would strongly recommend this substance to the profession as a safe and sure antiseptic, and in many respects superior to iodoform or other powders of this class.

THE STIMULATING TREATMENT OF PNEUMONIA.

BY S. L. ABBOT, M.D., BOSTON,
Member of the Board of Consultation of the Massachusetts General Hospital.

In the *London Lancet* of April 4th of last year, was an interesting paper by Dr. Squire, strongly advocating the stimulating treatment of pneumonia, in which a hospital case was cited in illustration of its efficacy. The patient was "so far gone" that the physician in attendance gave him up as in a hopeless condition. The interne and the nurse, however, determined he should not die if they could help it, and accordingly plied him with brandy, as much as they could get down. The result was that he took in twenty-four hours thirty-two ounces of brandy, with decided benefit, and following up the treatment the man got well. A good abstract of the paper is published in the *Therapeutic Gazette* of August 15th.

This case brings very forcibly to my mind one under my care in the Massachusetts General Hospital some years since. The patient was a respectable young woman, eighteen years old, who at the time of her admission, was suffering from double pneumonia, the lower half of both lungs being solidified. She was of course in a very critical condition, requiring that she should be held up by all the means that could be employed. She absolutely refused, however, to take any form of nourishment, even milk. Happily, she did not object to stimulants, so I directed the nurse to give her as much good French brandy as she could

persuade her to take, properly diluted, watching carefully for any sign of over-stimulation.

On the following morning I was astonished to find that she had taken half of a so-called quart-bottle of the stimulant (a little short of sixteen ounces) without the least discomfort or over-excitement. The treatment was continued, the same quantity of brandy being given her each of the two following days, with no bad result. On the morning of the fourth day whiskey was substituted for brandy, and of this she took three-quarters of a quart-bottle each day for four successive days, without the least discomfort or over-stimulation. On the morning of the eighth day there was a decided change for the better, and the patient absolutely refused to take a drop more of liquor. This was accordingly omitted, and she took without any objection, milk and other light nourishment such as her condition called for, and her recovery was complete and rapid. It was interesting to note how readily the patient, who was not an habitual user of stimulants, took them as prescribed — how entirely free she was from any appearance of intoxication while taking them — and her instant rebellion against them when the demands of nature had been satisfied. She took no drugs from the beginning to the end of her illness. I will only add that I cannot recall any other case in my practice in which I have thought it advisable to give stimulants so freely. Of course I have used them very often, as the case required, but never so far as I can remember, to the entire exclusion of food and drugs.

Medical Progress.

REPORT ON DISEASES OF CHILDREN.

BY T. M. ROTCH, M.D., AND A. H. WESTWORTH, M.D.

TREATMENT OF SCARLET FEVER BY ANTI-STREPTOCOCCUS SERUM.¹

THIS publication is a *résumé* of studies made in ninety-six cases of scarlet fever in the Hôpital Trouman. It was taken for granted that the secondary infection in the severe cases of scarlet fever was due to streptococci, and that by means of inoculations with anti-streptococcus serum, this dangerous complication might be avoided. Of the ninety-six cases four died; these cases, however, had been received after the duration of the disease for a number of days. In two children who died in spite of the injections there were found present also Klebs-Löffler bacilli. The latter were found, together with streptococci, in fifteen other cases of scarlet fever. Two more of the fatal cases were suffering from uremic poisoning. There was still another death which was due to a double pneumonia as a complication. The results arrived at were the following: That the action of the serum is only temporary. The injections must therefore be repeated as often as an exacerbation takes place. The most marked effect of the injections is on the glandular swellings and the initial albuminuria. They do not, however, prevent the appearance of purulent albuminuria. The writer expresses the opinion for the present, that the remedy may do some good in scarlet fever cases.

RESULTS OF THE PATHOLOGIC ANATOMICAL EXAMINATIONS OF THE EAR IN MEASLES.²

F. Bezold after carefully conducted examinations for a number of years arrives at the following practically important conclusions: In not one case of death from measles was there missing at the autopsy a muco-purulent or purulent secretion in the temporal bones. With the exception of one case, where the process existed before the contraction of measles, there were present fresh inflammatory processes, confined in one case only, to the bony tube, in two cases to the tube and the floor of the tympanum. In all other cases there were collections of secretion, redness and swelling covering all the cavities of the middle ear. A spontaneous perforation of the drum membrane is not often produced by the otitis of measles. Injection of the vessels was slight, irregularly distributed and occasionally punctiform. The destruction of the drum membrane and the auditory canal occur more seldom, probably on account of the more protracted course of the inflammation, than we find in other forms of otitis, notably that occurring in scarlet fever. The otitis of measles is to be looked upon as an integral part of the systemic infection, and does not arise through extension from the nose into the Eustachian tubes, etc. In the greater number of cases the pus is again absorbed without having caused perforation of the membrane, or any injury even to the hearing. In a few cases the exterior of the drum membrane does not show any changes, but usually it is somewhat darker, and particularly in the posterior upper quadrant is of a diffuse livid-red color. Masses of pus may shine through in the intermediary zone of the posterior half, giving it a yellowish color, and usually it is slightly bulging here. Besides this, single radiating vessels are frequently seen, and in single cases a sinking of the drum membrane is observed. The surface becomes successively dimmer, often wrinkled, and on greater saturation by serum or thin liquid pus, raised vesicles are noticed. If a perforation takes place from the middle ear, the secretion will continue days or weeks. The perforation is seldom large, and always closes up again. With good treatment, hearing is restored even in the perforative form. In comparison with the forms of otitis which complicate other infectious diseases, the one appearing with measles is to be considered of a relatively mild character.

CONTRIBUTION TO THE CAUSATION AND THE STATISTICS OF PRIMARY TUMORS OF THE BLADDER IN CHILDHOOD.³

The author reports the clinical history and autopsy report of a case of primary sarcoma of the urinary bladder, occurring in a boy two and three-fourths years of age and collates the published cases of primary tumors of the bladder, up to the present time, which occurred in childhood. He was able to gather only thirty-two cases, including his own, thereby showing the rarity of the affection in early life. In thirty cases, where the sex was mentioned, twenty cases were males, and ten females; so that also in childhood, as in adult life, the male sex seems to be predisposed to this affection. As regards the age of

² F. Bezold: Der Kinderarzt, 1896, vii, 80. Pediatrics, October 1, 1896.

³ Steinmetz: Deutsche Zeitschr. f. Chirurgie, 1896, xxxix, 313, 336. Pediatrics, October 1, 1896.

the patients, children during the first five years of life are most frequently attacked. In twenty-nine cases, where the ages were recorded, there were twenty-three cases during the first five years of life (including one newly-born) and only six cases between the fifth and thirteenth years.

All the tumors belonged to the class of connective-tissue tumors. Fourteen (one case was a myosarcoma) were sarcomata. Thirteen are designated as myoma, but the author, in conjunction with Albarran and Fenwick, is inclined to believe that also these were probably sarcomata or myxo-sarcomata (most of these tumors having been diagnosed from their macroscopic appearances); so that the sarcoma must be looked upon as the predominating variety found in the bladder of children. Besides these, there are recorded one fibromyoma, one cystofibroid, one rhabdomyoma and two other tumors, which were not classified. In two of the cases there were present congenital deformities of the urinary organs, namely, one diverticulum of the bladder, and in the author's case a horse-shoe kidney. The seat of the tumors was usually at the neck of the bladder and its lower third, which may explain why dilatation of the ureters and hydronephrosis with implication of the kidney (pyelonephritis) was observed so frequently. Quite frequently (as in the author's case) a part of the tumor protruded into the urethra, and in females through the urethra into the vulva. Of twenty-six cases only one presented a solid tumor; in one case there were two tumors, but in all the others a great number was present. Nearly always cystitis, and hypertrophy of the muscular wall of the bladder were present, which latter fact might be of diagnostic importance on bimanual palpation of the empty bladder. Metastases were only mentioned in one case, a lymphatic gland the size of a hazel-nut being found at the lower end of the left ureter.

The course of the disease in the child differs from that of the adult, inasmuch as hematuria, which usually appears very early, is seldom found in the child (only four cases of hematuria are mentioned, in two of which it occurred at the very end, probably caused by the intense cystitis). More frequently the affection begins in children with difficult urination, — strangury, anuria, symptoms of stone, pain in the bladder and glans penis, causing the patient often to continually pull at the organ. The prognosis, as a rule, is fatal. Within ten weeks to three months from the first symptoms, death is induced by infection (cystitis, pyelonephritis) and uremia (hydronephrosis), in only one case, published by v. Linhart, the duration of the disease covered a period of two years. Operations were performed in fifteen cases, one case only, operated on by Billroth and published by Gussenbauer, which proved to be a solitary pedunculated myosarcoma, was successful. It may be that the prognosis in the future will become somewhat more encouraging, if an earlier diagnosis would lead to an earlier operation. It should be borne in mind, in this connection, that Albarran has often found a hematuria in tumors of the bladder which could only be recognized by a microscopical examination of the urine.

TUBERCULOSIS IN EARLY INFANCY.⁴

H. Kossel had the opportunity of observing twenty-two children, from the ages of two months to three

years, during their illness with tuberculosis. All of these cases ended fatally. There was also found at autopsy in fourteen children, who died from other causes, at the ages of from one and one-half to ten years, tubercular foci situated in the bronchial glands in ten cases, and in the mesenteric glands in one case. There were no symptoms of the disease manifested during life in these cases. Amongst the anatomical findings in these cases, the changes in the respiratory tract and its lymphatics were undoubtedly the most marked, and those of the digestive tract next. In the latter, the disease was primary in the intestines; in one child, eight months old, a tubercular ulcer of the ileum was found, together with tubercular infection of the mesenteric glands.

The observations made in numerous cases of extensive tubercular processes in infants only a few months old, seems to raise the question, whether an infection with tubercle bacilli may not have been possible during intra-uterine life. This question is not only of scientific interest, but also of great practical importance. The author thinks it noteworthy, as militating against infection before birth, that he never found older tubercular foci in the liver, into whose circulation all germs that are being carried by the umbilical vein must pass first. Moreover, these foci were always found in the lungs, or in those glandular environments whose main roots were nearest in connection with the outer world, that is, the bronchial or mesenteric lymph-glands. The author comes to the conclusion that in tuberculosis of early infancy, at least, we have to admit an infection with the micro-organism, in the first few months following birth, by contact. It is quite obvious that infants whose parents expectorate the infectious germs of tuberculosis in large quantities, are very likely to admit tubercle bacilli by way of the respiratory system, or the digestive organs, into the economy. In the course of the investigation, the discovery was made, that among the children from one to ten years of age, who were sent to the institution (usually for diphtheria), forty per cent. were suffering from latent tuberculosis. Does it not seem about time, says the author, to follow the lead of the Americans, and employ practical measures against the spread of tuberculosis.

AN ADDITION TO THE THERAPEUTICS OF SUMMER DIARRHEA IN INFANTS.⁵

O. Reinach made a report from the H. v. Raunkes' clinic, on the use of serum, for its blood-thinning qualities, in severe cases of gastro-enteritis. The sterilized serum of the cow was used, though horses' serum is now employed, since Landois proved that the latter was perfectly harmless to the human blood corpuscles. The experiments were made on fifteen infants, ranging in age from fourteen days to nine months, all of them very serious cases, some nearly moribund. These infants were all artificially fed, and were suffering from acute digestive disorders, and treatment was commenced two or three days after the beginning of the disease, when they had already rapidly lost flesh. Four of the patients died, two with severe lobar pneumonia, and two of severe follicular disease of the large intestine. In the rest of the infants the serum treatment showed a favorable influence on the disease. The general appearance improved.

⁴ H. Kossel: *Der Kinderarzt*, 1896, vii, 19. *Pediatrics*, Oct. 1, 1896.

⁵ O. Reinach: *Münch. med. Woch.*, 1896, xliii, 421. *Pediatrics*, December 1, 1896.

the eyes became clearer, cyanosis diminished, the vessels of the skin became injected, and digestion was rapidly improved. Nourishment consisted of thin rice water during the first twenty-four to forty-eight hours.

From ten to twenty-six cubic centimetres of serum were injected under the skin of the thorax. No eruption ever occurred at the site of puncture. In one case an eruption similar to measles, lasting two days, appeared after two weeks, without any fever. Fever was noted in two cases after the injection, and in one case rose to 38.5° C. The rapid improvement of the digestive power and of the stools, in most cases, was partly due without doubt, to ingredients of the serum, which vitalized metabolism. Especially does common salt exert an influence on glandular activity. The fact that albumin is injected subcutaneously in the serum is probably of importance, when we remember that in these cases nourishment was withheld for a number of days. In twenty cubic centimetres of the serum, the albumin amounted to one and five-tenths grammes, equal to the amount of albumin contained in fifty grammes of undiluted cows' milk, or one hundred and fifty grammes of mothers' milk. This, of course, is but a small quantity. It is, however, possible to divide a larger portion of serum into two parts and inject it. At all events, it seems to some purpose that even small quantities of nourishment should be brought into the body where all food has been stopped by the mouth. Further researches in this direction will be made.

New Instruments.

AN AXOMETER.¹

BY CHARLES H. WILLIAMS, M.D., BOSTON.

It is often desirable to measure the position in which a cylindrical lens is being worn, and with the weaker lenses of half a dioptric, or less, especially when combined with a spherical glass, it is not easy to determine quickly and accurately, by ordinary means, the position of the axis of the cylinder. For this purpose I have arranged a simple instrument, as follows:

A box (or tube), sixteen inches long by one and a half inches square, has at one end A, a thin brass diaphragm with a very small hole at its centre. The size of this hole is important for the proper working of the instrument, and my best results have been obtained by drilling through the thin brass plate with a number-nine sewing-needle, so that the point projected about one-sixteenth of an inch through the plate. The middle of the box at B is cut out so that the lens to be measured can be inserted in the double-spring C, which holds the lens at right angles to the axis of the box. At D is a plano-convex lens of three and a half inches focus, and at E is a smaller box which slides into the larger one and carries on its outer end a ground-glass screen F, on which the rays of light from the hole in the diaphragm are focused in a point. If a cylindrical lens, either convex or concave, is placed in

the path of the rays at C, the image on the ground-glass screen, instead of being a dot, will be drawn out into a fine line, and the direction of this line will be at right angles to the axis of the cylindrical lens. A circular rotating frame G is placed outside the ground-glass, and across the diameter of this frame is stretched a fine wire, which, by moving the frame, can be made to correspond to the direction of the line of light

focused below it on the glass; a pointer attached to the frame will then show on a scale S (Fig. II), the angle at which the axis of the cylindrical lens is placed, as compared with the horizontal line of the instrument, the scale being graduated through 180 degrees from left to right on the upper half of the circle, the zero being on the horizontal line to the left. The horizontal line of the instrument is shown by a fine wire at H, passed from side to side through the centre of the box.

To use the instrument, the patient is requested to put on his glasses, and while they are on his face in the usual position, a ruler, or any straight edge, is held against his nose in front of the glasses, so that its upper edge stands horizontal and about in front of the centre of the glasses. This edge marks the horizontal line of the glasses as worn, and is indicated on each glass by touching them with a fine-pointed tooth-pick moistened with ink, making two dots on each glass about three-quarters of an inch apart, all the dots being on the horizontal line. The glass, so marked, is now placed in the spring C, the sliding-box at E is removed, and a white card or paper is placed behind the glass, so that on looking through the box at E, the glass can be shifted so as to bring the dots to coincide with the wire H, which marks the horizontal line of the instrument. Replacing the sliding-box at E, removing the card, and holding the end of the box A near a gas flame, a line of light will be seen focused on the ground-glass F, provided the lens is a simple cylinder, and by moving the wire in the frame G to coincide with the line of light, the angle at which the lens is worn can at once be read off on the scale of the instrument. If the prescription calls for a glass at 90° , and this test shows the angle to be 93° , or some slighter variation from 90° , it will probably not make an appreciable difference to the patient, for in putting the glasses on, from time to time, especially with eyeglasses, he will probably make as much or more variation than this, but if the amount is considerable, often reaching 5° to 10° , or more, and if there is discomfort on using the glasses, the error will need correcting. The glasses must be placed in the spring so that the

¹ Read at a meeting of the American Ophthalmological Society, July 16, 1896.

observer looks through them in the same direction as the patient does when he is using them.

If we wish to measure the axis of the cylinder in a compound lens, it will be necessary to place in the box at K a spherical lens from the trial case that will neutralize the spherical component of the compound lens, otherwise the line of light will not be focused on the screen.

When measuring a concave cylinder it is easy, not only to get the direction of its axis, but also its power when less than two or three dioptries; for if we withdraw slowly the sliding-box at E, we find a point where the rays of light will be brought to a focus in a line at right angles to the first line, and a scale on the side of the sliding-box will then show the power of the concave portion of this glass, it being necessary to draw the sliding-box further out, the higher the power.

Since writing the above the instrument has been improved by making the tube longer so that the direction of the line of light with the weakest lenses can be more easily seen and the direction of the axis measured. The sliding tube is made to push in or draw out from the zero point so that the power of cylinders up to one dioptric convex or concave can be measured, in addition to direction of the axis of any cylinder. The spring clip for holding the lenses has been improved. A better method has been devised for bringing the horizontal line of the glass to correspond to the horizontal line of the instrument without removing the sliding tube, and the whole apparatus has been made of light metal and mounted on a convenient stand. Such an instrument can be obtained from Messrs. Miller & Welch, 38 West Street, Boston, Mass.

Reports of Societies.

THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

REGULAR Meeting, November 17, 1896, the President, DR. JAMES R. CHADWICK, in the chair.

DR. W. T. COUNCILMAN spoke on the subject of
MATERNAL IMPRESSIONS.¹

DR. J. J. ENGELMANN was interested in the ground taken by Dr. Councilman, with which he can hardly agree. He recalled a case of a woman pregnant eight months, brought to a Philadelphia hospital badly burnt. Within a week she gave birth to a child that showed similar marks as of a burn and in corresponding situations. This, to say the least, is a startling coincidence. This and cases cited by Fordyce Barker have made him believe in maternal impressions, although he cannot understand how they are brought about.

DR. J. B. SWIFT referred to a case that came under his observation where a woman eight months pregnant struck her thumb-nail with a hammer. The infant born at full term had the thumb of the corresponding hand discolored, and the nail, as in the case of the mother, finally came off.

DR. EDW. REYNOLDS said that it was difficult to get away from the evidence presented by the large number of cases reported by competent men, which seem to prove the existence of maternal impressions on the fetus.

DR. C. M. GREEN spoke of a family in which extra toes were hereditary. He also referred to a mulatto child whose back resembled in its hairy growth the back of a rat. The mother, it was said, stepped on a rat going down the cellar stairs, and believes in this way she marked the child.

DR. C. E. STEDMAN referred to the frequency with which mothers think their children will be marked compared with the rarity of birth-marks and monsters, and also to the fact that if a child is marked the mother then proceeds to think up some impression she may have had to account for it.

DR. J. G. BLAKE said he had never been able to connect any malformation with a maternal impression. He referred to a child born without arms which he had shown on two occasions to the Society.

DR. C. W. TOWNSEND mentioned a case of Dr. W. L. Richardson's where in two pregnancies the patient experienced much nervous dread, thinking the child would be marked, as she had seen many deformed and diseased people. Both of these children were perfect. At the third labor she remarked to Dr. Richardson that she had no fear of the child being marked, not having worried about it, and moreover she had seen no disagreeable sights. This child, however, was marked.

DR. J. R. CHADWICK said that his scepticism had been somewhat staggered by Fordyce Barker; but it seems more reasonable to attribute these very exceptional cases to coincidences rather than to maternal impression.

DR. E. G. CUTLER, by invitation, read a paper entitled

SOME REMARKS ON UMBILICAL HERNIA, ESPECIALLY AS OBSERVED IN ANCIENT SCULPTURE.²

Recent Literature.

Over the Hookah, the Tales of a Talkative Doctor. By G. FRANK LYDSTON, M.D., Professor of Genito-Urinary Surgery in the Chicago College of Physicians and Surgeons, Professor of Criminal Anthropology in the Kent College of Law, etc. Sold by subscription only. Profusely illustrated from the author's designs by C. EVERETT JOHNSON. Chicago: The Fred Klein Publishing Co.

This striking and profusely illustrated volume of 600 octavo pages, is a collection of short stories with a medical flavor, often more or less fantastic in character, purporting to be the talks of an old physician of varied experience with a friend who is a medical student.

They are said to be most of them original or founded on real incidents, and, according to the author, if the characters seem overdrawn, it is their own fault, and not that of his description. Certain of the character sketches are in the form of dialogues between the doctor, who acts as interlocutor or "middleman," and whose Socratic function is to ask questions calculated to bring out the desired side of the "character" which he wishes to display. The hypothetical questions of the middleman are sometimes somewhat suggestive of a ventriloquist's questions to his puppet, laboriously planned and carefully impressive in their style.

² Publication reserved.

The Histo-Pathology of the Diseases of the Skin. By Dr. P. G. UNNA. Translated from the German, with the author's assistance, by NORMAN WALKER, M.D., F.R.C.P., Ed. Edinburgh: William F. Clay. New York: Macmillan & Co. 1896.

It would be impossible in the space allotted to us to attempt a serious criticism of this colossal work from the pen of Dr. Unna. Several exhaustive critiques have appeared in journals devoted especially to cutaneous medicine, of which that by M. Darier in the *Annales de Dermatologie et de Syphiligraphie* is worthy of especial praise. Dr. Unna has preferred to work through the whole subject of cutaneous pathology anew rather than to present a critical digest of the existing literature. He acknowledges that it has been impossible to do this completely, in the five years during which the book has been in process of making, and that its amplification must be left to the future. As it stands to-day, however, it is a monument to his industry and application, and a mere turning of its leaves must excite the wonder of all dermatologists.

As was to be expected from the general scheme of the work, the author's own views and studies are usually the only ones presented, and in many instances a decided position is taken from the examination of a very meagre amount of material. Dr. Walker has certainly rendered a great service to dermatologists outside of Germany in translating this work, as Unna's style makes a perfect understanding of his thought extremely difficult even to those who have a good knowledge of the German language.

To the dermatologist Unna's work is indispensable for reference; for however much we may disagree with him, and however hastily he may seem to us to settle many questions on insufficient evidence, he has certainly made some distinct contributions to our knowledge. To the reader not versed in dermatology, or to one who has not at least to some extent followed Unna's literary career of late years, the book will prove baffling and worthless. Almost a completely new nomenclature has been introduced by the author, expressive oftentimes of beliefs that are shared by few or no other authorities, and a reference to previous articles of his own would be necessary before even a partial understanding could be reached.

In addition to the double colored plate of nineteen illustrations of histological appearances brought out by Unna's especial methods, that appeared in the German edition, we have forty-two illustrations in the text, made from preparations from Unna's laboratory, which add much interest to the reading matter.

The Medical and Surgical Uses of Electricity. By A. D. ROCKWELL, A.M., M.D. Illustrated with 200 engravings and one plate; 8vo; pp. xvi, 612. New York: Wm. Wood & Co. 1896.

This work is practically the ninth edition of Beard and Rockwell's well-known work, but, as it has been thoroughly revised, and much new matter added, and as the late Dr. Beard died soon after the second edition appeared, it has been thought proper to publish the present edition under Dr. Rockwell's name alone. The familiar plan of the work has been retained, but the illustrative cases have been omitted to make room for the various additions. The section on static electricity has been entirely rewritten and much enlarged, and a chapter on the Röntgen rays gives proof that the new edition has been brought up to date.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JANUARY 14, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

TREATMENT OF CANCER OF THE STOMACH.

THE purpose of the present article is to consider the treatment of cancer of the stomach from a medical point of view. That relief and even cure have in some instances been obtained through surgery is admitted. Most cases, however, remain from the first under the care of the physician, and for reasons deemed sufficient, surgical means are not tried.

The medical treatment has ever been pre-eminently disheartening. The physician makes his diagnosis, and feels that his mission is virtually over. In hospital wards it is customary for the medical attendant to stop occasionally at the bedside of the patient to call attention to the peculiarities of the case, but the therapeutic part of his clinical remarks does not detain him long.

Since the discovery of improved methods of diagnosis through the chemical examination of the contents of the stomach, there has been a reaction against the do-nothing régime, and a feeling has become prevalent that something more can be accomplished for the amelioration of these unfortunate patients. This has found its latest expression in an article by Prof. Albert Robin in the *Bulletin Général de Thérapeutique*.¹

In the first place, though it is rendered certain that there are no absolute chemical criteria of gastric carcinoma, yet in the great majority of cases there is absence of digestive power and of the normal acid-secretion ("apepsia and anachlorhydria"). Lactic acid is generally found in excess, and sometimes butyric and acetic. The digestion of albuminoids is wholly insufficient and nil; the stomach "has become an inert receptacle in which aliments stagnate and are not utilized." It has been found, however, that amylaceous matters are fairly well transformed, for sugar is constantly detected in the contents of the stomach after the ingestion of starchy food; the lactic acid comes from this source. Hence, then, a leading indication is to diminish or suppress in the daily fare of these patients, albuminoid foods, and to prescribe a starchy

¹ December 15, 1896.

diet. By fulfilling the latter indication, vicious fermentations are in a great measure arrested. The complete interdiction of animal food is, however, not called for when the pylorus and intestine are not involved, for there is then the possibility of ready transit of ingesta into the intestine, whose power of digesting albuminoids is well known. Meat powders and peptones may be permitted in these cases of integrity of the pylorus; even tender fowl, lean, tender meat of whatever kind, white fish, meat jelly, etc. Azotized feculents, as boiled mashed peas, pea soup, bean porridge, also cooked fruits, cold biscuits, pilot bread, etc., may often be eaten with impunity, while fresh bread, pastries, cheese and sugar give great distress by the fermentations which they occasion. Patients suffering from gastric cancer should drink but little, and eat but three times a day.

Robin proposes numerous drugs in the treatment of this disease, and believes that more benefit may be obtained from a judicious use of pharmaceutical remedies than many practitioners are aware of. He gives condurango as a stomach tonic—not because it is antagonistic to the cancer. Half an ounce of the bark is steeped in a pint of water; it is somewhat reduced by boiling, strained, and given in the dose of a dessert-spoonful just before meals. Tincture of *nux vomica* in five-drop doses may be substituted. Sometimes he gives just before meals a powder containing three grains of ammonium chloride, five of sodium bicarbonate, and two of Dover's powder.

To favor digestion, the patient is directed to take at the end of every meal a few swallows of a solution of hydrochloric acid in water, 1 to 1,000; at the middle of the meal, a "cachet" containing ten grains pepsin, and two each of maltine and pancreatin.

To prevent fermentations, a few grains of sulphur or naphthol are given after eating. Lavage of the stomach is sometimes indicated, especially when there are abundant acid vomitings, much pain and stenosis.

Vomiting is a common symptom, and is sometimes incoercible. Among the remedies which Robin proposes, is cocaine. Give five minutes before each meal, a teaspoonful of a solution containing fifteen centigrammes (two and one-half grains) to one hundred and fifty grammes (about five ounces) of water. Sometimes a teaspoonful of menthol water or chloroform or peppermint water will do as well.

A favorite prescription of his for the vomiting of gastric carcinoma is the following:

Picrotoxine	5 centigrammes
Hydrochlorate of morphia	5 centigrammes
Sulphate of atropia	1 centigramme
Cherry laurel water	10 grammes

M. Sig. Dose, two to eight drops a few minutes before the principal meals. An opium suppository may sometimes with good effect be employed in the morning on awakening.

For severe hemorrhages, the main reliance is on ergotine, employed subcutaneously, or in solution along with gallic acid and turpentine.

For the relief of pain, the main reliance must still be on subcutaneous injections of morphine. In such

a disease as this, the fear of making the patient a morphomaniac need hardly be entertained.

For the pyrosis, a powder of magnesia, bicarbonate of soda, bismuth and opium is perhaps as good as any that can be prescribed. The obstinate diarrhea which attends many cases of gastric cancer will often yield quite promptly to an old-fashioned pill, consisting of calomel, ipecac and opium, one-sixth grain each, to be taken every six hours.

For the cachectic state, the glycono-phosphate of soda is recommended; this may be taken by mouth or introduced subcutaneously.

BICYCLING AND APPENDICITIS.

SINCE bicycling became popular, we have heard little else but praise of the exercise on the part of physicians. The bicycle has been the means of giving country air and sunshine to the city-penned shop-girls, compelled by their business to breathe more or less pure carbonic acid during long working-hours, has cleared the liver and loosened the bowels of the dyspeptic, expanded the lungs of the pale scholar, bent by over-study, and by its tonic effect upon the muscles of the thigh and pelvis has well-nigh done away with "female weaknesses" in women who ride.

Just as we are comfortably settling down, however, to a belief in the bicycle, not only as a safe and healthy exercise for almost every one without serious valvular heart lesions, but also as a cure for a large majority of the minor functional ills which flesh either is heir to or acquisitive of, we are roused from this sense of security by the reported observation that bicycling is a frequent cause of no less formidable a disease than appendicitis.

"More than one surgeon," writes the editor of the *Medical Press and Circular*, "on either side of the Atlantic, has commented upon the comparative frequency of this lesion in cyclists. Now that the non-cyclist is the exception, a large proportion of the cases must of necessity occur in persons more or less addicted to 'the wheel,' but there seems to be some ground for suspecting that, under certain circumstances, direct contusion of the appendix by an actively contracting psoas muscle, may set going the morbid process described as appendicitis. It is suggested that any special exertion, such as riding up hill, may expose the cyclist to the risk of twisting the appendix over the sharp, hard edge of the contracted psoas muscle. The immediate result is desquamation of epithelium over a crease in the mucosa, thus opening the door to infective agents. Some swelling ensues, leading to compression of the appendix within its inelastic sheath, and this is the starting-point of an attack of appendicitis."

Dr. Byron Robinson, of Chicago, has recently,¹ as a result of his observations at a large number of autopsies, adduced a relation between the peri-cecal

¹ Medical Record, November 28, 1896.

and peri-appendiceal adhesions so frequently found, even in cases in which there has been no attack of perforative appendicitis, and the mechanical trituration of the overlying bowel by the contracting psoas muscle.

If, as the slang phrase goes, "there is anything in this," then bicycling, an exercise which certainly requires very frequent and vigorous contractions of the psoas, would seem at least a reasonable cause for peri-cecal and appendiceal inflammation, even perhaps of occasional typical attacks of appendicitis.

In patients who have had an attack of appendicitis, cycling would be admirably adapted to the disturbance of adhesions, and the lighting up of another attack.

It is to be hoped and perhaps expected that fear of appendicitis will cause no great diminution in the popularity of bicycle exercise, but that pain in the right side in bicyclists may be carefully investigated by the physician, who should bear in mind the at least possible connection between the bicycle and appendicitis.

After all, there is the reassuring reflection that one has appendicitis without bicycling, and that one may bicycle without having appendicitis.

MEDICAL NOTES.

ITALIAN HONORS FOR BEHRING.—The King of Italy has conferred upon Dr. Behring, by virtue of his discovery of diphtheria antitoxin, the grand cordon of the crown of Italy.

INFLUENZA IN GALVESTON.—It is reported that influenza is epidemic at Galveston, Texas. Although there are very large number of cases, the disease is of a mild form, and very few deaths.

JENNER MEMORIAL.—A public movement is on foot in London to raise funds to establish some institution in connection with the British Institute of Preventive Medicine as a memorial to Jenner.

CESSATION OF THE "UNION MÉDICALE."—After fifty-one years of dignified existence, the *Union Médicale* ceases its publication with this year. The three principal editors, Richelot, Richardière and Eugène Rochard, join the editorial staff of the *Bulletin Médical*.

A NEW ELEMENT.—M. P. Barrière announces the discovery of a new element, which he calls "lucium" in the mineral monazite. It is reported that the announcement has been confirmed by other competent chemists, and that the atomic weight of the new element is 104.

THE GERMAN CONGRESS OF INTERNAL MEDICINE.—The Congress of Internal Medicine to be held at Berlin next June, will discuss chronic articular rheumatism, address by Bäumler; epilepsy, address by Unverricht, and exophthalmic goitre, address by Eulenberg.

PLAGUE REPORTED ON AN AUSTRIAN STEAMER.—It is reported in the daily papers, that an English lady, *en route* from Bombay to Trieste, on an Austrian steamer, is ill with symptoms of plague. The steamer is quarantined.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the two weeks ending at noon, January 13, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 214, scarlet fever 73, measles 226, typhoid fever 21.

NO SPITTING IN STREET-CARS.—The subjoined notice has, by order of the Board of Health, been posted in all the cars of the West End Street Railway Company, Boston: "The Board of Health adjudges that the deposit of sputum in the street-cars is a public nuisance, source of filth, and cause of sickness, and hereby orders that spitting on the floors of street-cars be, and hereby is, forbidden." Above this order is posted a copy of the statute stating that the fine for infringement of an order of the Board of Health is one hundred dollars.

LEAD-POISONING FROM METALLIC STOPPERS.—Cases of lead-poisoning having come to the knowledge of the Massachusetts Board of Health, among persons who had made use of carbonated waters and syrups put up in glass bottles with metallic stoppers, the Board has caused analysis of such stoppers to be made, with the result that percentages of lead were found varying from 50.7 to 3.5 in the stoppers used by 29 bottling companies. Twenty other samples contained three per cent. and less of lead.

NEW YORK.

DIPHTHERIA AND PUBLIC SCHOOLS.—An outbreak of diphtheria has occurred at Elmsford, a village near Tarrytown-on-the-Hudson, and in consequence the local Board of Health has ordered that the schools be closed and services in the churches discontinued. The disease is said to have been spread by a child who attended school while in the early stages of the affection, the true character of which was apparently not recognized.

MILK-BORNE SCARLET FEVER.—A localized epidemic of scarlet fever, in which the source of trouble has been traced to milk, is reported from East Orange, New Jersey. Within a very short time it was found that the disease had appeared in sixteen houses, with from one to four cases in each. The physicians in attendance reported the outbreak to the local Board of Health, and an investigation by Dr. Winthrop D. Mitchell, the health officer, brought to light the fact that all the families in which scarlet fever had appeared were supplied by one milkman. On further inquiry it was found that the son of this milkman had recently had a severe attack of the disease, and that while convalescent had been about the premises where the cows were kept and no doubt had assisted in the milking. It was therefore concluded

that the contagion had been transmitted by means of scales of desquamating epidermis which had dropped from the lad's hands into the milk; and at a meeting of the Board of Health held January 8th stringent measures were adopted to prevent a further spread of the disease. It is interesting to note that the origin of the outbreak from the milk supplied by the dairyman mentioned was proved almost beyond the possibility of a doubt by the fact that one of the patients who was attacked was a lady confined to the house, who at the time was on an exclusive milk diet and, as far as known, was in no other way exposed to the risk of contracting scarlet fever. A peculiar feature of the outbreak is that a large proportion of the cases have occurred in adults, from twenty to thirty-seven years of age, rather than in children.

THE LOW MORTALITY-RATE CONTINUES.—The mortality in the City of New York, while showing some little increase of late, is still unusually low for this season of the year. During the week ending December 26th but 603 deaths were reported, and in that ending January 9th there were 738. There has been a slight increase in the deaths from scarlet fever, diphtheria and measles, but the mortality from typhoid fever was the same in both weeks, seven. The deaths from pneumonia increased from 80 to 98, those from phthisis, from 83 to 99, and those from Bright's disease, from 47 to 64. During the week ending January 9th three deaths were reported from influenza.

Miscellany.

AN OUTBREAK OF CHOLERA IN AN OFFICERS' MESS.

"ON July 13, 1896," writes Hankin, in the *British Medical Journal* of December 26, 1896, "thirteen persons sat down to dinner at an officers' mess at Saugor, a station in the Central Indian provinces." Two days later nine of them were attacked by vomiting and diarrhea, which in these cases developed into typical cholera, and two of these died. Hankin does not explain how, considering the unlucky number, any better result could have been expected, but proceeds to relate the curious and highly interesting manner in which he found after much investigation that the cholera bacillus had gained an unbidden entrance to the dinner-party.

The drinking-water was exonerated by the facts, that the mess was provided with a Pasteur filter, and that few of the members ever drank water. None of the servants of the mess came down with cholera, except one who had eaten the remains of a chocolate pudding, and who died on the same day as did the two guests of his master.

Into the details of the exclusion of other methods of invasion we need not go. Suffice it to say that investigation of the method of preparing chocolate pudding showed that it was made of gelatine dissolved in water, with the addition of egg, milk, sugar, various coloring agents, and essence of vanilla to hide the taste of the cook's fingers. It was then strained through a

piece of muslin, and placed in a mould in ice. It will be seen that boiling does not enter into its preparation. Hankin found by experiment that the gelatine used in making the chocolate was an admirable culture medium for the bacillus. Now how did the original bacillus get in? An investigation of the habits of Indian cooks afforded an easy explanation.

"Every cook possesses a piece of muslin through which he strains all sauces, custard, blanc-manges, etc. This muslin, owing to its frequent use, is apt to acquire a bad smell. If this becomes too pronounced, the food acquires a disagreeable flavor, and the cook is likely to be fined. In order to avoid this the muslin is occasionally sent to the wash, I suspect, even in cases in which the dish-cloths are never thus exposed to the risks of infection with the microbes of water-borne diseases. As has been shown above, the constituents of the chocolate pudding had been strained through such a piece of muslin."

It was found that a mess servant had washed these "dish-cloths" of muslin in a running stream just before the fatal mess, and that five or six cases of cholera had occurred in some huts near the place where the washing had been done and draining into the stream. The cholera bacillus was detected in the sand near the river bank where the dish cloths were laid out to dry. Thus the fatal number, thirteen, was exonerated and the cholera microbe found guilty of causing the death of two officers of Her Majesty's service and one servant.

Hankin found as a result of his experience during the summer, that numerous European officials and military officers died of cholera and enteric fever in India, while the private soldiers were singularly free from the disease.

"To the best of my knowledge," he writes, "in the whole of the Bengal Command during the present rainy season, cases of cholera among soldiers have only been reported from two stations, and in one at least of these places the infection appears to have been contracted while the men were on the march. I believe this remarkable immunity of the British soldier, as contrasted with the relative liability of the British officer and civilian official, is due to the strenuous efforts now being made by officers of the Army Medical Staff to sanitize the soldiers' cook-houses.

"The kitchens in India most in need of reform are those attached to the officers' messes of British regiments. These are private institutions not subject to official control. It is high time that officers of the Army Medical Staff should be invited to undertake the task of sanitating these kitchens. It will, I think, be clear from the facts described in this paper, that the complete prevention of cholera is rapidly becoming a matter for specialists. The ordinary mess president is no more a specialist than the average subaltern is an epicure. Together they produce and consume horrible delicacies that are often a severe strain on the digestion of their guests."

He further says:

"It is as unusual as it is to me unpleasant, to go out to dinner and then to criticise the *menu* in this way; but I hope it will be admitted that the occasion is one for plain speaking rather than for ceremony. When dining at an officers' mess the other day, I noticed that the soup was putrid; but my hosts, with sturdy appetites bred of healthy exercise, consumed it with perfect content. The whipped cream poured over the apple pie had the abominable taste of dirty dish-cloth, noticed, I believe, by no one but myself. My host had heard vaguely of my recent researches, with the result that the next item on the *menu* had the title *crème à la microbe*. It was chocolate pudding. After dinner I inspected the mess kitchen. To all appearance it

was perfectly clean, and the mess president pointed out to me with pride a long row of enamelled iron saucepans with which he had replaced the more usual degchies, apparently under the idea that they could be less suitable than the latter for the breeding of microbes.

"Nine or ten subalterns in this regiment have had enteric within my recollection, so the need of some precautions was obvious; but I very much doubt whether the mess president had chosen the precaution most necessary. Though in many cases, so far as he himself is concerned, the British officer can only be stimulated into sanitary zeal by attendance at a long series of funeral parties, his care of the private soldiers under his charge is altogether admirable."

The results of the efforts of the mess president to have his kitchen cleaned are amusing, according to Hankin's description, which is as follows:

"If the ordinary mess president attempts to improve his kitchen, he is likely to do more harm than good. For instance, he will issue orders that the floor is to be washed every day, instead of once a week. Under existing conditions, cleaning kitchens in Upper India is a dangerous process. Cooking the sahib's dinner is regarded as a somewhat unclean occupation by most natives. Mohammedans do not like it because we eat bacon, and Hindus look askance at the business because we eat beef. For these reasons native cooks in general are of rather low caste and low standing; hence they are apt to stand on what little dignity they have, and consider it beneath them to clean the floors of the kitchen in which they work; consequently the sweeper has to be called in to do the business. In Upper India there are no sewers. The sweeper is a man who fulfils the functions of a sewer; he is apt to carry about outside him what sewers in other countries carry about inside them—namely, dangerous microbes. I have elsewhere published an account of a very clear case in which I proved that the sweeper was introducing cholera microbes into the cookhouse because of his methodical habit of reserving one broom for clean work, such as sweeping out barracks, and another broom for dirty work, such as cleaning out latrines and cookhouses. Those who know India will agree with me that stopping this abominable custom may not be so easy as it appears on the surface. It is possible that the mess president would most readily achieve this object by insisting that the cook should sleep on the kitchen floor, if possible with his head in a degchie. The mess president would then have an assurance that he at present lacks, that neither the one or the other would be cleaned with the broom that is used for the servants' latrines."

Correspondence.

RAILWAY CAR HEATING.

Boston, December 26, 1896.

MR. EDITOR:—A recent canvass, made at random, with the object of ascertaining the views of the medical profession of Boston regarding artificial heating of passenger cars, reveals a practically unanimous opinion: it is excessive. Fifty-eight, of a total of sixty-one consulted, signed a petition addressed to the railroad commission, asking for a modification of the rules governing the heating of electricies; one refused to sign because he thought no artificial heat should be employed in the street-cars of the city; one because he seldom rode in them, and consequently had never noticed excessive heat; and one because he was not prepared to say what temperature the heaters would effect, although of the opinion that the heat is often excessive. A diligent inquiry among laymen resulted in the same general conclusion, with but one exception.

The present rules require that artificial heat shall be employed in all outside temperatures below 50° Fahrenheit, and that not less than 50° or more than 60° shall be main-

tained inside the cars. This is obviously defective, in that it is based chiefly on inside temperature when thermometers cannot be hung where they will register with any degree of accuracy, and are not employed. Regulations are, therefore, subject to the caprice or idiosyncrasy of conductors and passengers.

The manager of the principal street-railway of Boston expresses a willingness and desire to operate the heaters by exact conditions of outside temperature as registered by the thermometer, and the railroad commission exhibit a commendable disposition to formulate such rules as will most contribute to the health and comfort of passengers. Apparently the matter is in a fair way for satisfactory change.

At least fifty of the physicians who signed the petition expressed regret that steam railroads were not included in the protest against excessive heating, as they considered them the greater offenders, some saying "the heat is often infernal," others that they "dreaded a railroad journey because of the heat and foul atmosphere of the cars."

To properly regulate the heating and ventilating of steam-cars is difficult. The railroad commission has nothing to do with the subject, unless in so far as it is charged with the duty of requiring all passenger-cars to be equipped for steam-heating; and railway officials claim that "it is impossible to maintain a healthful and satisfactory temperature in the cars so long as they are obliged by statute to use steam heat that can never be less than 212°; that proper ventilation is impossible so long as the public enjoy the right to open and close doors and windows at pleasure, or while there are as many different opinions on ventilating and heating as there are passengers in the car."

Every fair-minded man must at once admit that these conditions make it extremely difficult to formulate satisfactory rules governing the employment of artificial heat, to provide an ample supply of fresh air, and at the same time exclude disagreeable draughts. For many years railroad managers have labored in efforts to surmount these obstacles, recognizing their own interest and the public interest to be identical. They have expended large sums of money in experiments, with the object of making railway journeys as agreeable and comfortable as possible, but with unsatisfactory results both to themselves and the travelling public.

Good ventilation is possible with a variety of systems in use, if train-men and passengers permit them to be employed. This is often demonstrated in passing a stock train. Cars are immediately filled with an offensive odor, which almost as quickly disappears. The closing of ventilators is therefore the only reasonable ground of complaint of the foul atmosphere of the cars, which many persons prefer to endure rather than be subjected to cold draughts from open ventilators while in a state of active perspiration occasioned by the excessive heat of the cars. Under these conditions an extremely feeble current of air is recognized as an intense draught in contact with the moist surface of the body, due to rapid evaporation of moisture. In my office I have observed a difference of twenty-two degrees a number of times, between a wet and dry bulb thermometer hanging side by side, under the influence of very gentle fanning.

It is therefore obvious that the maintenance of lower temperatures in the cars will diminish the consciousness or appreciation of draughts. It would also lessen the foul odors uprising from dirty clothing in close proximity to steam-pipes, and the exhalations from diseased lungs and dirty bodies of passengers. A reduction, however, is not easy to accomplish while passengers have a voice in the management of heating and ventilating. One person rides to the train, and feeling chilled, wants ventilators closed and heat turned on. Another walks, and pronounces the same car excessively hot. The train-man cannot please both, so exercises his own judgment; that is just as likely to be faulty through an excess or insufficiency of food and clothing, or his general physical condition. The average passenger, reasonably fed and clothed, makes no complaint, but patiently suffers because of the extreme views of a few

who are always in evidence; and there appears to be no remedy except the adoption of rules that neither trainmen or passengers shall be permitted to violate.

Before deciding on what degree of temperature should be the maximum, tests should be made with thermometers in different parts of a car, for it is often painfully apparent that when a thermometer registers 70° on the wall of a car, the temperature where the passenger is seated is far above this, because of closer proximity to the steam-pipes.

It is unnecessary to affirm to readers of the JOURNAL that a low temperature is preferable on hygienic grounds to a high temperature; but until the public realizes that "taking cold" is not so much a consequence of being chilled, as it is a consequence of being heated in a foul atmosphere loaded with infectious inhalations from diseased lungs, it will be difficult to adopt a sufficiently low temperature to insure the most healthful conditions. Many recent observations in street-cars, with and without artificial heat, convince the writer that with the ordinary amount of clothing it is not desirable to heat the cars above 50°, that 60° is uncomfortably warm, and 40° uncomfortably cool for the usual short journey; but, when we remember that riding in carriages and sleighs in temperatures far below this point, is not attended with other than beneficial results, we must conclude it is better the temperature should be a little too low than a little too high.

Very truly yours,
HENRY J. BARNES, M.D.

DEATH-CERTIFICATES OF LIFE INSURANCE COMPANIES AND ENDOWMENT ORDERS.

DORCHESTER, January 2, 1897.

MR. EDITOR:—I would like to call the attention of your readers and the medical directors of life insurance companies to the important question of what constitutes a "satisfactory proof of death" to be filled out by the medical attendant on the demise of an insured person.

I bring this up because I believe that many companies ask questions they have no business to ask.

Any physician is perfectly willing to give a satisfactory proof of death; but when the company goes on, after getting it, and asks questions relating to the personal and clinical history of one's patient, it is calling for what no physician has any right to give. Such questions as the following, taken from a prominent life insurance company's certificate are what I object to:

10. Had deceased any other disease, acute or chronic, or had he ever had any injury or infirmity?

12. (a) Did deceased use stimulants or narcotics? (b) To what extent (whether daily or in what quantity)? (c) State whether, in your opinion, the disease or death was due to the use of stimulants or narcotics?

Or, again, from another company:

13. (a) State any other matters known or observed or learned by you pertaining to the medical history of the deceased? (b) or which in your judgment contributed directly or indirectly in any degree to the cause of death? (c) Is there anything material to the case which has not been brought out by above questions? If so, state same fully.

More could be added, but these illustrate my point.

One benefit order has, with its subdivisions into *a, b, c*, thirty-eight questions, of which six refer to proof of death and the rest are of such a nature as would help them dispute the claim.

No self-respecting and respected physician, who has the confidence of the families under his care, has any right to answer or to be expected to answer such questions. Refusing to answer them usually causes delay and inconvenience to the claimants.

A law requiring all life insurance companies and endowment orders doing business in this State to use as a certificate of proof of death an established set form, would be of great service, not only to the physician, but to the insured as well.

Very truly yours,
SAMUEL CROWELL, M.D.

CONGENITAL TUMOR OF THE VAGINA.

OAKDALE, MASS., January 6, 1897.

MR. EDITOR:—On the 1st of December, 1896, I attended Mrs. M. E. in her first confinement. The labor was normal in every respect, and the woman was delivered of a female child of six and one-half pounds. The following day I was told by the nurse that the child had passed no water, and that something was wrong "down there." I then made my first careful examination of the child. The vulva was considerably redder than the surrounding tissues, and upon separating the labia almost the whole inclosed space was found to be occupied by a mass projecting from the vagina. The meatus urethrae and clitoris were forced into the anterior commissure of the labia. The tumor was paler than its surroundings, and firm to the touch. There was a colorless, viscid discharge from the vagina, bathing the tumor and external genitals. A dull curette passed around the tumor showed it to be about one and one-half inches long by three-quarters of an inch through. It was attached to the posterior wall of the vagina by a pedicle about three-quarters of an inch from the orifice. Pressure upon the tumor caused a passage of water from the bladder through the meatus urethrae. During the following week the child passed urine normally, as it probably had during the first twenty-four hours.

A month later there is less redness of the vulva, the labia minora are in their normal position, the discharge is still present, and the vaginal orifice occupies about its proper share of territory, but projecting from it is still the tumor, apparently reduced in size one-third.

Very truly yours,
EDW. D. WILLIAMS, M.D.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JANUARY 2, 1897.

Cities.	Estimated population.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

Deaths reported 2,967; under five years of age 925; principal infectious diseases (small-pox, measles, diphtheria and

croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 313, acute lung diseases 585, consumption 347, diphtheria and croup 148, typhoid fever 50, diarrheal diseases 49, whooping-cough 20, scarlet fever 19, measles 14, cerebro-spinal meningitis 7, erysipelas 6.

From whooping-cough Philadelphia 6, New York 4, St. Louis 3, Chicago and Baltimore 2 each, Boston, Pittsburgh and Cambridge 1 each. From scarlet fever New York 8, Philadelphia 4, Boston and Cincinnati 2 each, Chicago, Pittsburgh and Providence 1 each. From measles New York 5, Chicago 4, Boston 2, Philadelphia, Fall River and Lynn 1 each. From cerebro spinal meningitis New York and Lynn 2 each, Boston, Lowell and North Adams 1 each.

In the thirty-three greater towns of England and Wales, with an estimated population of 10,846,971, for the week ending December 26th, the death-rate was 17.0. Deaths reported, 3,545; acute diseases of the respiratory organs (London) 284, diphtheria 68, whooping-cough 64, measles 60, fever 32, scarlet fever 29, diarrhea 26.

The death-rates ranged from 11.0 in Croydon to 31.8 in Plymouth; Birmingham 17.9, Bradford 16.9, Gateshead 18.0, Hull 22.0, Leeds 18.7, Leicester 16.8, Liverpool 20.2, London 15.1, Manchester 19.5, Newcastle-on-Tyne 18.4, Nottingham 17.7, Sheffield 17.4, West Ham 15.6.

METEOROLOGICAL RECORD

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JANUARY 9, 1897.

M. S. GUEST, passed assistant surgeon, detached from the "Massachusetts," January 9th, and ordered to the "Vesuvius," January 12th.

L. W. ATLEE, passed assistant surgeon, detached from the "Richmond," on relief and ordered to the Naval Hospital, Philadelphia.

W. F. ARNOLD, passed assistant surgeon, detached from the "Enterprise" and ordered to the "Richmond."

R. P. CRANDALL, passed assistant surgeon, detached from the "St. Mary's" and ordered to the Naval Hospital, Norfolk.

LEWIS MORRIS, assistant surgeon, promoted to passed assistant surgeon from June 27, 1895, and ordered to the "Essex."

H. M. WELLS, medical director, retired January 20th.

J. R. TRYON, medical inspector, ordered to examination for promotion, January 11th.

G. P. BRADLEY, surgeon, ordered to examination for promotion, Washington, D. C., January 18th.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE FIFTEEN DAYS ENDING DECEMBER 31, 1896.

WASDIN, EUGENE, passed assistant surgeon. Granted leave of absence for three days from January 1, 1897. December 22, 1896.

WHITE, J. H., passed assistant surgeon. Directed to inspect unseizable property at Stapleton, S. I., N. Y. December 29, 1896.

MAGRUDER, G. M., passed assistant surgeon. Granted leave of absence for nine days from December 23, 1896.

STEWART, W. J. S., passed assistant surgeon. To proceed from Washington, D. C., to Colonial Beach, Va., on special temporary duty. December 26, 1896.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

The next lecture will be given on Thursday, January 21st, at 8 P. M., by DR. ABNER POST. Subject: "Late Hereditary Syphilis." The profession are invited.

SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The Section for Clinical Medicine, Pathology and Hygiene will have a regular meeting at the Medical Library, 19 Boylston Place, January 20, 1897, at 8 P. M.

Eight to half-past eight o'clock: Short Communications by Drs. Ewald, Stone and White.

Half-past eight o'clock: Dr. H. N. Heineman, of New York, "The Schott Treatment of Heart Disease at Bad Nauheim." Discussion opened by Dr. A. L. Mason.

February 17, 1897. Dr. E. G. Cutler: "Gastrodiaphany."

E. W. TAYLOR, M.D., Secretary.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.—The ninety-first annual meeting of the Society will be held January 26, 27 and 28, 1897, in Jermain Hall, Albany, commencing at 9.15 A. M., on the 26th, and ending at 1 P. M. on the 28th.

Communications relating to the presentation of papers or to any changes in the provisional programme, should be sent to the Business Committee: Seneca D. Powell, Chairman, 12 West 40th Street, New York; Willis G. Macdonald, Albany; Ernest Wende, Buffalo.

RECENT DEATHS.

WILLIAM SHEPHERD BEAUMONT, M.D., M.M.S.S., died in Jamaica Plain, January 7, 1897, aged thirty one years.

DR. WILLIAM H. PANCOAST, of Philadelphia, died January 8th, after an illness of several weeks. He was born in Philadelphia in 1835, and was graduated from Haverford College in 1853. In 1856 he received the degree of M.D. from Jefferson Medical College. In 1874 he was made a professor in the Jefferson Medical College, succeeding his father in that position. He was elected president of the Medico-Chirurgical College in Philadelphia in 1886, and continued in that position until a year ago when he resigned. He was the first president of the International Red Cross Society of Philadelphia and was a surgeon in the Union Army in the Civil War. At the time of the death of the Siamese twins Dr. Pancoast secured their bodies and demonstrated that if the bond uniting them had been severed in their lifetime death probably would have resulted to both of them.

DR. A. J. FULLER, a leading physician of Bath, Me., died January 10th, aged seventy-four years. He was first vice-president of the American Medical Association and for eighteen years president of the Bath Board of Trade.

DR. THEODORE G. WORMLEY, the distinguished chemist and toxicologist, and professor of these branches in the medical department of the University of Pennsylvania, died on the 3d inst. of stomach trouble, after an illness of several months. He was born in Wormleysburg, Pa., on April 1, 1826, and in 1849 was graduated in medicine from the Philadelphia Medical College. In 1852 he was called to the chair of chemistry and natural sciences at Capitol University, Columbus, O., which he held until 1865, and was also professor of chemistry and toxicology in Sterling Medical College from 1854 to 1877. In 1877 he was called to the chair of chemistry and toxicology in the Medical Department of the University of Pennsylvania which he has since held.

DR. EDWARD PEARSON ELLIOT, first assistant in the Danvers Insane Hospital, died January 10th. He was a native of Boston and was graduated from Harvard College in 1875, and from the Harvard Medical School in 1882. He served as house-officer in the City Hospital two years, and studied abroad two years. He had held his position as assistant in Danvers during the past twelve years.

BOOKS AND PAMPHLETS RECEIVED.

Heredity, Its Significance in Life Insurance. By Thomas H. Rockwell, M.D. Reprint. 1896.

An Initial Report from the Neurological Laboratory of the Philadelphia Polyclinic. Under the direction of Aloysius O. J. Kelly, A.M., M.D. Reprint. 1896.

The Quantitative Estimation of the Rennet-Zymogen, Its Diagnostic Value in Certain Diseases of the Stomach. The Importance of the Saliva in Gastric Digestion. By Julius Friedenwald, A.B., M.D., Baltimore. Reprints. 1895-96.

Lecture.

THE CLASSIFICATION OF BENIGN TUMORS OF THE BREAST.¹

BY J. COLLINS WARREN, M.D., LL.D., BOSTON.

THE great frequency with which the breast is afflicted with cancer, makes any lesion of that organ a source of great anxiety to the patient and to members of the family. The importance, therefore, of a correct knowledge of all the growths of this region is such that it seemed to me that this subject would be a suitable one for one of the evening lectures of this winter's season.

The subject of this evening's lecture will therefore be a review of the different forms of tumor of the breast, more particularly the benign tumors, in order to prepare the way for the differential diagnosis between them and the malignant forms of disease of the breast.

In studying out this subject a little more exhaustively than I had hitherto done, I was struck with the lack of unison in the opinions of different writers on this subject. There seems to exist an imperfect knowledge of the pathology of the various diseases of the breast, more particularly the tumors, even among the writers of the highest authority. In going over the work, in sifting out the opinions of different authors, in summarizing them, and then in taking a general view of the whole situation, I think that I have arrived at conclusions which I should not have arrived at under any other circumstances.

We will begin at the development of the gland, and trace somewhat briefly the earliest forms of development of the gland, the period of full maturity, and the gradual decline and atrophy of it in advanced life.

The mammary gland is, as you know, an appendage of the skin; as one writer has expressed it, a sort of highly specialized sudoriparous gland. It begins as a slight outgrowth of the rete Malpighii into the cutis vera in the early weeks of fetal life, and at the period of birth it has already formed a number of radiating ducts with pear or club-shaped ends, some fifteen to thirty in number, radiating from the common point at which the outgrowth has started from the surface.

If we study the development in the embryo of mammals, we see some interesting features in the process of development which have a bearing on what we have to say about morbid growths later on. I have here three embryos of the pig of about one month's growth. An examination of the abdomen with a lens shows a faint continuous line running from the axilla to the groin on either side of the abdominal cavity, and, as the fetus grows, this line works up more nearly on to the front of the abdomen. The formation of the numerous udders, or of the mammary glands, takes place by a growth of this layer of the ectoderm, as it is called, and by a process of differentiation a thickening at three or four parts of the line occurs. Finally, we find that the line itself has disappeared, and in its place we have a row of nipples.

I have said that at birth the gland had a sort of stellate or radiating appearance, being composed of a series of ducts with pear or club-shaped ends. An examination of them shows considerable activity within the tubes at the time of birth. There is a prolifera-

tion of the epithelium, a shedding of the epithelial cells and an accumulation of a certain amount of granular *débris* in the interior of these ducts at birth. It almost seems as if there were something akin to an inflammatory process going on in the breast at this period. This activity in the epithelium produces a dilatation of the tubes, so that there is a sort of ectasia, and finally it is so marked that it becomes at the end of the first year a cavernous structure lined with a pavement epithelium. No material change in the appearance of the gland takes place after this until the age of puberty is reached, and then we find, of course, an increase of growth again in the gland, and we notice this condition not only in the female sex, but occasionally also in the male. I have been on several occasions consulted by mothers of young boys about fourteen years of age, for a distinct swelling and tenderness of the mammary gland coming on about the age of puberty.

Comparatively few acini are developed at the ends of the ducts and smaller tubes at this period.

Outside of the ducts and tubes we find the development of a hyaline connective-tissue stroma, having parallel bundles of fibres, which is quite a marked feature; and this basement stroma is distinctly different from the connective-tissue stroma of the gland proper itself. It is quite rich in nuclei, more or less transparent, and different in its nature from the ordinary connective tissue which we get in the stroma of the mammary gland—an interesting point to remember, because it again has a bearing upon the development of certain morbid growths.

The next stage in the development is the development of the acini, and this takes place by a sort of budding process, a growing out into the surrounding connective tissue; and here we get the physiological homologue of true adenoid tissue, that is, a new development of typical gland tissue, by a growing out of little processes of epithelium, at first solid, and later containing spaces which represent a true gland growth. At the time of pregnancy this development of acini takes place at an enormous rate. After lactation is over the acini collapse, but they do not disappear; and of course they remain there to be distended again at the next period of lactation.

After the period of full maturity of the gland has passed, we come to the period of decline, which, of course, becomes more marked at the menopause; and we have there another important and interesting condition to study. We find then that the acini began to be absorbed and to disappear; and what we have finally left is merely an elongated tube which generally ends in more or less of a club-shaped extremity, and we have connected with the end histological structures which show the atrophied remains of previously existing acini of the gland. At this time also we often find a slight amount of desquamation of epithelium and granular *débris* in the interior of the tubes, as if this period of metamorphosis of epithelium was disturbed in its process of growth and decay, and was stimulated to a little greater activity at certain points than it had been before.

As the gland structures of the breast atrophy and disappear, connective tissue and adipose tissue come to take their place, and we finally have a breast containing merely the larger ducts, a small amount of fat and connective tissue, but little or no proper gland tissue.

¹ An Evening Lecture at the Harvard Medical School.

I think that you will agree with me that there is a certain parallelism in the development of the breast, as I have sketched it, and in the development of the different types of tumor at different periods of life. In the first place, I have spoken of the condition of the mammary gland at birth, and later on at the period of puberty, the great development of the gland, the peri-acinous and peri-tubular growth of the hyaline connective tissue, etc.; and we sometimes find that development occurring in a precocious and somewhat exuberant way, and the condition which is known as infantile hypertrophy illustrates that peculiar condition of the gland. I have here a photograph of a child with fully developed breasts and quite well developed figure, whose age at the time the photograph was taken was two years and seven months, a case kindly placed at my disposal by Dr. Marcy. The sexual instincts of the child were strongly developed. Another unusual form of development of the mammary gland is a condition known as gynecomastia, that is, development of a female breast in the male. Williams represents such a breast in a well-formed young man, and Henry describes the case of a man who had very well-formed breasts, and who assisted his wife to suckle a family of eight children.

I have here the photograph of such a case. This man evidently exhibited himself as half man and half woman. He has allowed the hair on one side of the body to grow and on one side of the lip. It is evident that he is a typical example of gynecomastia, having the ordinary figure of the man in every respect except in regard to the right breast.

Another form of malformation is that known as polymastia, and all I have to do is to recall to you the development of the milk line in the pig and in the lower mammalia to show how it comes about that this condition of polymastia or multiple breast occurs in certain cases. In this diagram I have indicated the line which you have seen, the milk line, and where the nipples would be likely to occur perhaps in the lower mammalia and possibly in man's earliest ancestors, as Williams has indicated in his monograph on the breast. Cases of breasts upon the thigh and back, of supernumerary nipples in these localities have been quoted, but it is probable that the majority of supernumerary breasts develop themselves along this line; and we see here in this case, which is an example not only of polymastia, but of diffuse hypertrophy, that we have the development of supernumerary gland tissue along just that line, and if we could have lifted up that breast in the photograph a little bit, we should have found beneath it a supernumerary nipple. This patient came under my observation at the hospital a year or two ago, when she was at about the middle of her pregnancy. The photograph was taken at that time. The second photograph was taken about the time of confinement in the lying-in hospital. After the confinement had taken place the breasts diminished very greatly in size. Dr. Anthony, of Bradford, afterwards took her through a second confinement, and found renewed enlargement of the breasts and subsequent subsidence. In her second confinement she was allowed to nurse the child, and the breast secreted an abundance of milk.

Diffuse hypertrophy is a condition which this patient also serves to illustrate, but really a more typical example was that which I have represented in my work on surgical pathology and which was published

by Professor Porter in the "Proceedings of the American Surgical Association," where the breasts were much more largely developed, and where he succeeded in removing by amputation both the breasts very successfully. The anatomical condition of diffuse hypertrophy of the breast seems to differ in different individuals. In some cases it appears to be simply an increase in the amount of glandular tissue. In other cases it seems to be an increase in certain constituent parts of the mammary tissue; and in the case of Dr. Porter, which was examined by Dr. Whitney, there was an interstitial growth giving rise to that cystic type of breast disease which we shall speak of presently, so that there seems to be a certain amount of tumor formation in such breasts. In the second case to which I have just alluded there did not seem to be any lobular growths which indicated any such form of growth, but a general diffuse enlargement of the breast—gigantism, if we may say so, of the mammary gland.

Now we will take up more characteristically tumor-like growths of the gland, and attempt to trace the analogy between them and the changes seen in the mamma at the different stages of its development and decline. I shall speak first of fibroma of the gland, which comes in the early period of the life-history of the adult mammary gland; and then of the cysto-adenoma of the gland, which comes in the period of the full development of the acinous portion of the gland, the more strictly glandular structures; and finally, about the cystic degeneration of the gland, which comes in the period of senile change and decline.

First, in regard to fibroma. If you remember, I called your attention to the fact that at the age of puberty there was a growth of hyaline tissue about the tubes and lobules of the gland. Fibroma of the gland, according to Billroth, is developed from that structure. These tumors appear in early life shortly after the period of puberty. There are two forms of fibroma, the solid and the cystic. In the solid forms, where there are no cysts, the average age is said to be about twenty-three years, and in the cystic forms about twenty-six years.

I will speak first of the cystic, which is, perhaps, the most common and most characteristic. I have here a diagram of that growth stained with a double stain of eosine and hematoxylin. The epithelium is stained purple, and the fibrous tissue pink; and we see in between these long slits, which are so characteristic of the cystic fibroma, or intra-canalicular papillary fibroma as it is sometimes called, this hyaline tissue. With the active growth of this tissue there is a stretching and distortion of the ducts of the glands, the acini having been but very imperfectly developed at that period of life, and these long narrow slits are thus developed. We see but little glandular structure in such tumors. These tumors reach about the size of an egg or a little larger, are more encapsuled, and when excised do not, as a rule, recur. They are generally single, but sometimes multiple. I saw yesterday a young lady operated upon three years ago for a tumor of this kind of the right breast, and find that she has another of the same character growing in the left breast. She is now about twenty-one years old.

Gross speaks of a solid fibroma of the breast, and I presume he refers to the little hard lobular tumors, about the size of a walnut, which Sir Ashley Cooper

has described as "chronic mammary." We make a section and we find none of the slits. We find a few fragments of gland-tissue, and in the interstices between the gland structure dense fibrous tissue. This is a comparatively harmless growth, does not become inflamed, increases to the size of a walnut and there remains. The patient experiences a little pain and tenderness at the period of the catamenia, but otherwise has no trouble. Lately, at the hospital, I had the opportunity of examining such a tumor which had been twenty years in the breast of a woman who came for another affection entirely, and she said she had experienced no trouble from it whatever.

We come next to a form of tumor which has to do more particularly with the gland structures of the breast; and here we find a tumor growth more distinctly in the middle period of life, the average age being about forty-three. Here we find very distinctly gland structures existing, and this is a section taken from one of these growths kindly prepared by Dr. Whitney and drawn by Mr. Kaula. You see these growths are somewhat polypoid or villous, and they have been called villous papilloma by some authors, and cystic adenoma by others. They are full of little spaces more like acini than tubes, though sometimes they become more oval and elongated like tubes and are lined with a layer of epithelium. It is evident that these tumors grow from small acini and very small ducts of the gland. They develop in different ways, according to different authors. Billroth suggests that there is a very active growth of epithelium, and quite a number of acini develop in which the epithelium afterwards breaks down and leaves cysts of considerable size. The stroma of the gland takes a comparatively small part in the development of the tumor; and so we see little of the connective tissue as compared with the great mass we see in the fibroma of the gland. Sometimes these cysts develop to a very great size; and here is one of the most marked types, which was removed at the hospital a few days ago, and we see one of these villous tumors developing in it.

Gross has almost denied that there is such a thing as true adenoma of the gland. He is very strict in his definition of what adenoma should be. He has seen, he says, but two examples of it himself, and has only eighteen examples of pure adenoma on record. I think that he has attempted to isolate too completely the gland structure from the other structures of the breast. You see that in so complicated an organ as the breast, when one part grows the other must grow to certain extent, and we get complicating and confusing pictures somewhat difficult to interpret; but if we hold fast to the point of origin of the growth we do not have that difficulty. If we hold to the acinus growth in the cystic adenomas, we shall have an ample explanation of the peculiar papillary character of the growth, which is not a papilloma any more than its surroundings oblige it to be, and therefore we should properly classify this as a true form of adenoma, modified of course to adapt itself to the structure in which it grows. This form of tumor appears at the time when the acini are in a most active stage of development, that is, in the forties. It is a softer tumor than the fibroma, and does not grow much larger. One of the characteristics is a sanæous discharge from the nipple. We can understand how that would occur in vascular growths; by the break-

ing-down process we should have little hemorrhages which would cause discharge from some neighboring excretory duct.

I pass by the lipoma, chondroma and osteomas of the gland as extremely rare forms of tumor, and tumors which have nothing in particular to do with the mammary gland, and come to the kind of tumor, or more properly disease, which we find in the declining stage of the gland; in that stage when the acini become atrophied and are replaced by connective tissue, and the tubes are somewhat dilated towards their extreme ends into club-shaped dilatations, and are lined with a somewhat thickened and desquamating layer of epithelium. The gland going through this process of atrophy, with substitution of connective tissue and fat for active gland structures, this disturbance of epithelium may easily become so altered in certain parts as to disturb the regular process of involution, and consequently constriction of the ducts leads to the formation of cysts. Now these cysts may be either single, confined to one lobe of the gland and growing to the size of a walnut, or they may permeate the whole of the gland. This is cystic degeneration, as it is sometimes called—a condition which exists probably in a slight degree in the majority of declining breasts. Some pathologists call this condition, of which I have an example here, chronic mastitis with retention cysts. This is a breast split open to show the whole interior of the gland; and you see here the whitish mammary tissue and these little cysts full of greenish material, and some again quite large, and as in this case so extensive that the whole breast had to be removed on account of the complete degeneration which had taken place. Some authors think this is a form of cysto-adenoma but there is no development of the glandular structures, as it belongs to the period when the parenchyma of the gland is atrophied and in a quiescent state, and when the gland itself is in a state of involution; and therefore it is to be looked upon rather as a degenerative process than an actively developing one. These cysts occur at about the time that malignant disease develops, and consequently they are the subjects of great solicitude to the patients suffering from them; but the characteristic symptom is the presence of a large number of little pea-like bodies diffused over the gland, sometimes in one breast, and sometimes in both breasts, accompanied with considerable pain, caused by a hyperesthesia of the nervous filaments going to them.

I should like to say a word about the treatment of these cysts. When there is a single cyst a puncture will sometimes suffice for a cure, as the cyst will collapse and never fill again; but where the disease is more extensive and involving the whole of the gland, then it is perhaps necessary to remove the whole or portions of the gland. If the cysts do not enlarge, they may be allowed to remain, as they will probably give no trouble and many such a breast can be saved from the knife if a correct diagnosis is made. Why should these cysts have this peculiar color? The walls of the cyst being in a state of glandular irritation, the epithelium breaking down, the vessels become thrombosed through hyperemia or perhaps constriction of their lumen, and little extravasations of blood take place, and we have hematoidin crystals and granules of fat and broken-down tissue that give them this peculiar appearance.

An affection which is likely to be mistaken for

this is one known as mastodynia or neuralgia of the breast. That sometimes accompanies this cystic degeneration of the breast, and sometimes is entirely independent of it. I think we see it at times with a certain amount of hyperemia, and perhaps a temporary enlargement of the breast without any actual structural change. These cases are extremely hard to manage, the patients becoming hypochondriacal; but the pain is usually not accompanied by any serious disease.

I have not said anything of chronic mastitis of the breast. I have left that to the last not to have it confused with any of the other affections mentioned. We may have an inflammation of the breast, and a chronic as well as an acute one. I shall say nothing about the acute inflammations. The chronic form is one which may occur and be accompanied by a considerable growth of connective tissue such as we have in the cystic degeneration. In chronic mastitis we find great growth of the interstitial tissue and destruction of the glandular structures. Billroth represents, and Williams copies from him, a form of shrieking mastitis which has all the appearance of atrophying scirrhus. Occasionally we do have a chronic inflammatory process of the breast going on to destruction of the breast. It may occur in early as well as late life. I remember a nursery maid who came to me twenty years ago with a lump in the breast. I removed it, and found no trace of malignant disease. I made the diagnosis of chronic mastitis. Presently she appeared with a similar lump in the other breast and I explained to her that she had not anything which it was necessary to remove.

Nevertheless, she had it burned out afterwards by a caustic process. She is still, so far as I know, in robust health. I think such cases are not very common, but they are to be taken into account in making a diagnosis of malignant disease of the breast.

I have not time to speak of tuberculosis or cold abscess of the breast. I think I have said enough to give you perhaps a little more intelligent idea of the origin of benign tumors of the breast and of the different types which we may expect to find at different periods of the life history of that organ.

DEDUCTIONS FROM HOSPITAL WORK IN ABDOMINAL SURGERY, WITH A REPORT OF FORTY-FIVE CASES.¹

BY F. W. JOHNSON, M.D.,

Gynecologist at Carney, St. Elizabeth's and Woman's Charity Club Hospitals.

THE following forty-five abdominal operations were done during the spring of 1896, at the Woman's Charity Club, St. Elizabeth's and Carney Hospitals.

There were nine hysterectomies.

Of the forty-five, four died; two following suprapubic hysterectomy for carcinoma, and two following celiotomy for tubercular disease of the tubes and ovaries. The two deaths following hysterectomy were at the Woman's Charity Club Hospital.

One (Case II) died of sepsis. The operation was a long one, and the patient was much exhausted by it. On the right side the disease had extended outside the uterus, infiltrating the right broad ligament as far as

the ilium. Breaking-down carcinomatous tissue could be dug out with the finger. This was a fruitful source for the sepsis.

The other (Case IV) died from shock. She was very much exhausted from long-continued loss of blood, by a long and difficult operation, and by a mortal dread of the operation. She took ether very poorly. Several times during the operation the pulse and respiration stopped, and when I had finished she was cold, and I supposed she was dead. Four of us worked over her for two hours before she began to rally at all, but spite of all we could do she died in thirty-six hours.

In the two celiotomies for tubercular disease of the pelvic organs, death was caused by sepsis. One occurred at the St. Elizabeth's Hospital (Case I), the other at the Carney Hospital (Case II). In both cases it is presumable that they became infected by the pus that escaped into the peritoneal cavity from the ruptured tube. In Case I gauze drainage was used.

For suture material within the abdominal cavity, catgut was used as much as possible. By using an absorbable material for ligatures, we avoid the trouble which so often begins weeks or months after silk has been used in the abdominal cavity, and continues until the silk is gotten rid of through the line of incision, bladder or intestines. I have had it escape by all these routes. In one case the intestine became adherent to the knot of silk used in tying off the left tube and ovary. Long-continued suppuration, with severe pain, necessitated a second celiotomy. It was found that the silk knot had worked its way into the intestine, leaving a long fistulous track.

Resection of the diseased and perforated intestine was successfully done by Dr. S. J. Mixer. Now that small and medium-sized catgut can be made perfectly sterile without impairing its strength, there is no excuse for using silk. I do not think it is safe to trust those who make a business of sterilizing suture material. If you do trust suture material sterilized by others, you will sooner or later certainly come to grief. In the sterilization of suture material, eye-servants should never be employed.

I have found two reliable methods for making catgut sterile. Catgut prepared by either of these methods is perfectly sterile. Both Dr. J. H. Wright and Dr. E. A. Darling of the Harvard Medical School, have examined catgut made sterile by these methods, and have pronounced it free from bacteria. I have never had suppuration follow the use of catgut thus prepared.

In both processes the gut is soaked in the ether for several days. It is then cut into the desired length, each length being thoroughly stretched (the stretching prevents kinking and twisting, which is so very annoying). The gut is then soaked twenty-four hours in absolute alcohol, to take out as much of the water as possible. It is then covered with a solution of bicromate of potassium in absolute alcohol (15 grains to the pint), and remains in this twelve hours.

In Process No. 1 each length is coiled up, done up in waxed paper, and put in an envelope which is sealed. The sealed envelopes are put in a dry oven, and baked for one hour at a temperature of 100° C. This removes all the moisture, and thus prevents further heating, making the gut brittle. On the following day the sealed envelopes are baked three hours at a temperature of 140° C. The gut is now ready for use. The envelopes are kept in a glass jar.

¹ Read before the Obstetrical Section of the Suffolk District Medical Society, November 4, 1896.

An assistant tears open one end of an envelope, undoes the waxed paper without touching the catgut, and hands it to the operator. In this way the gut is touched by nobody, and touches nothing until picked up by the fingers of the operator.

I consider this by far the neatest and most satisfactory way.

In Process No. 2, which is the one recommended by Dr. R. T. Morris, of New York, the gut is placed in ether and alcohol, as in Process No. 1; then it is placed in a jar and covered with a 1 to 4,000 ethereal solution of corrosive sublimate, and kept in this for a week. With sterile forceps it is then put in a sterile jar and covered with a solution of bicromate of potassium in absolute alcohol (15 grains to the pint). After staying in this solution twelve hours it is transferred with sterile forceps to a sterile jar containing 1 to 4,000 alcoholic solution of corrosive sublimate. It is now ready for use.

The two objections to gut prepared by the second process are that the storage jar must be opened at every operation, and the consequent danger, though it be very slight, of infecting the contents of the storage jar, and the gut itself is slippery and difficult to tie.

Soaking it in the solution of bicromate of potassium makes it strong and durable.

In dealing with the broad ligaments, I have given up the Staffordshire knot, the interlocking suture, and the shoemaker stitch.

Where the broad ligament is thickened, a great deal of force is required to draw the ligature tight enough to stop the bleeding and prevent slipping. Only large-sized catgut will stand this strain; and I am afraid of the large-sized strands, as the best authorities agree that it is difficult to sterilize the centres. Puckering of the broad ligaments often causes discomfort and pain, and compression of the nerves in the stump often requires a second celiotomy.

Since last fall I have given up the above-mentioned methods of suturing except in a few cases where I used silk, and I have removed tubes and ovaries, or tumors, by the following method: The ovarian artery on one side is tied with a single strand of small catgut; then the broad ligament is cut with scissors, below and parallel to the ovary and tube, up to the horn of the uterus. Each artery is clamped as cut, or the arteries supplying the ovary and tube are tied in the broad ligament with fine catgut, below where the ligament is to be divided. The tube and ovary, which are now dangling from the horn of the uterus, are removed after ligating the tube at the uterine horn with fine catgut, the uterine peritoneum being brought over the cut end of the tube, thus making it extra-peritoneal. The cut edges of the broad ligament are then sewed together with an over-and-over suture of catgut from the ovarian artery up to the uterus.

By this method there is no puckering of the broad ligament, no pain from pressure of nerve by ligatures, no danger of hemorrhage, and, as all raw surfaces are turned in, diminished liability to sepsis and to the formation of adhesions. If this method secured only immunity from *secondary hemorrhage* it would be sufficient to put it in advance of *all others*.

Learning that Dr. Halsted, of the Johns Hopkins Hospital, had for over a year sewed all his hernia wounds with buried silver wire, covered them with silver foil, and secured healing by first intention in every wound, I determined to try this method in clos-

ing abdominal incisions and Alexander wounds. Tests have been made by Halsted and Bolton as to the effect of silver on the growth of pyogenic organisms. If a Petri plate be inoculated with staphylococcus pyogenes aureus, and a small piece of silver leaf be placed in the centre of the dish, the following will be noted: Outside of the leaf and completely surrounding it, a perfectly clear zone will remain; just outside of this there will be a zone of slightly impaired transparency, but the rest of the plate will become uniformly cloudy because of the growth of micro-organisms.

Dr. Bolton has studied the inhibitory action of various metals upon the growth of organisms. He found that cadmium, zinc and copper were more powerful than silver.

In one case of abdominal section, done six months ago, I used buried silver-plated copper wire in fastening together the recti muscles and fascia, and there has been no irritation as yet.

Pure silver, if sterile, will give less trouble than any other kind of suture material.

Dr. Halsted does not hesitate to use buried sutures of silver wire in sewing tissues on the borders of infected regions. If put in doubtful tissues, and suppuration takes place, instead of sloughing out as other suture material does, thus keeping the wound open for a long time, it becomes covered over with granulations, and does not delay the healing.

Desirous of securing union, such as would avoid as much as possible the liability to hernia and the necessity of wearing an abdominal supporter, I have used during the last spring at the St. Elizabeth's Hospital, the over-and-over suture of catgut for fastening the peritoneum, first drawing the omentum down over the intestines and spreading it out over the fundus of the uterus. Then, if adhesions take place, they will be between omentum and parietal peritoneum, and not between the intestines and the parietal peritoneum.

Then buried silver wire for the recti muscles and fascia, animal tendon or catgut for the tissues between the skin and the recti muscles, and a buried catgut suture for bringing together the skin.

Two layers of sterilized silver-leaf were placed on the line of incision and on this the dressing.

In only one case when the above method was employed did we have so much as a stitch-hole suppuration. This case was one of tubercular disease, and suppuration destroyed union by first intention for about two inches in the centre of the incision. This method of suturing was used when drainage was employed.

Abdominal supporters were dispensed with where the recti-muscles and fascia had been fastened with buried silver wire.

This same method of closing the wound was employed in the Alexander cases. For some time I have been fastening the round ligaments in the Alexander operations with silver wire. No. 30 silver wire, if pure, will tie like silk.

All raw surfaces were covered over with peritoneum or seared over with a Paquelin cautery, to prevent infection and adhesions.

Drainage was avoided if possible. When in doubt, it was used, but I find myself using it less and less. If the pelvis cannot be sponged dry, or if there is oozing, it should *always* be used. Iodoform gauze may be firmly packed as a plug into the hollow of the

sacrum against an oozing surface or against one or both sides of the broad ligament; but if put in for oozing, it should be removed in from twelve to fifteen hours.

If possible, a plug of gauze should never be used for *bleeding*. Bleeding should be stopped by ligature, by sewing raw surfaces together or by the cautery.

I prefer for drainage a large-sized glass tube with no holes in the sides, which if properly taken care of, is absolutely free from all danger. Sometimes gauze is packed around the drainage-tube. Gauze does not give such free drainage as the tube, must be used longer, requires a bigger opening in the abdominal walls, is more likely to cause hernia, a sinus is more apt to follow its use, and without anesthesia, causes severe pain on removal. Gauze soils the dressing and the edges of the wound. With the glass drainage-tube the dressings can be kept as sweet and clean as when put on.

By bacteriological examination I have found the secretion in the glass drainage-tube on the third day free from pathogenic bacteria.

Where the intestine, bladder, or ureter is found seriously injured by disease, or where either is severely injured in separating adhesions gauze drainage through the incision should be used for a few days. Drainage should be used if there is fluid in the peritoneal cavity antedating the operation.

Gauze drainage should be used if the intestine has been opened and if there has been fecal extravasation. No drainage is called for where a healthy intestine has been repaired.

If septic pus or fluid gets into the peritoneal cavity at the time of the operation I do not believe drainage or irrigation of *any* kind will prevent peritonitis or save the patient. Fortunately, in the large majority of cases, the pus and fluid in the tubes and ovaries is sterile, as I have had verified by repeated bacteriological examinations. In abscess of the ovary the worse the fluid looks and the more rotten it smells, the more likely it is to be sterile.

Irrigation was used but a few times. Spouging dry with sterile sponges was considered far better. If pus or fluid escape after the patient is in the Trendelenburg position with the pelvis well walled off, very little spouging is needed to keep the parts dry and clean.

If non-sterile pus or septic fluid escapes into the peritoneal cavity, irrigation, no matter how practised, does little except increase the chances of septic peritonitis and death by disseminating the poisonous material among the intestines.

At the St. Elizabeth's Hospital during the past spring it was the routine practice during my service to give by the rectum before the patient came out of ether one quart of modified Ringer's fluid. It should be given through a long rectal tube from a fountain syringe, and before the patient comes out of ether, else so large a quantity of fluid will not be retained. Dr. J. G. Clark has pointed out that normal salt solution given before the patient comes out of the ether relieves the intense thirst so common after celiotomy, and it pretty much does away with the post-operative use of strychnia, atropia, digitalis and alcohol. During the operation, if the pulse got weak or rapid, one quart of modified Ringer's fluid was given by the rectum as above described, into the outer aspect of the thigh, into the buttock, or under the breast, through a

large-sized needle and by a Davidsou syringe, care being taken to keep the bulb of the syringe constantly under water thus preventing the injection of any air. Frequently a gallon of this fluid was used during an operation, and in a few severe hysterectomies for carcinoma eight quarts were injected.

The needle, after having been boiled in a soda solution is kept in alcohol.

The skin about the point of puncture is washed with soap-suds and then with alcohol.

Too much force should not be used in compressing the syringe bulb, else the cellular tissue will be torn and abscess may result.

If induration follows, the skin about the inflamed part is made clean, then a large piece of sterilized absorbent cotton is wrung out wet in absolute alcohol and fastened over the induration by rubber protective which has been perforated with small holes to allow of the slow evaporation of the alcohol. This is changed three times in twenty-four hours.

I know of nothing better than this to abort an ordinary abscess, the exudate often being absorbed in an incredibly short space of time.

Dr. Frank S. Locke, in the Physiological Department of the Harvard Medical School, first called my attention to his modification of Ringer's fluid. By adding chloride of calcium and chloride of potassium to normal salt solution the efficacy of the salt solution is much increased. They not only give the heart a better fluid to work upon, but they restore to the fluid in the vessels that coagulable quality which has been diminished or lost by hemorrhage. Dr. Frank S. Locke's modification of Ringer's fluid is prepared by adding three decigrammes of chloride of calcium and one decigramme of chloride of potassium to each litre of normal salt solution.

Codeia (half a grain) was given subcutaneously to every patient just as she was etherized. This diminishes shock by supporting the nervous system during the operation.

After the operation if there is much pain or restlessness two grains of codeia are given subcutaneously, and repeated every hour or two until relief. There is no danger in using this dose, and codeia will not constipate if it is pure. I have found after several years' hunt a manufacturer who every time puts on the market pure strychnia and pure codeia.

During my service in the winter of 1895 at all three hospitals my abdominal patients were made very uncomfortable by the routine practice of giving after every celiotomy eight grains of calomel in divided doses, followed two hours after the last dose by a large quantity of some saline. The first dose of calomel was given just as soon as the ether nausea had ceased. This was followed up by high turpentine enemas, enemas of molasses, or salts and glycerine, or soap-suds, until the bowels moved or gas had been freely passed.

This was done to get ahead of the dreaded paralysis of the intestine which was supposed to be the condition present when intra-abdominal trouble occurred after a celiotomy.

During this last spring nothing was given to move the bowels until the third or fourth day, unless the pulse went up to 115 or above, and stayed there some little time.

Twenty-four hours after each operation, unless gas had been passed, a high turpentine enema was given,

and, if needed, repeated every two or three hours. This was done for the patient's comfort.

No nourishment was given by the mouth for twenty-four hours.

The only change in technique was thorough scrubbing of the operator's and assistant's hands and the patient's abdomen with sterile brush and alcohol.

Every patient, beginning as soon as she entered, was given as a routine practice three vaginal douches a day of a two-per-cent. solution of creoline.

Just before each hysterectomy the vagina was made clean by washing it thoroughly with soap-suds, with a saturated solution of permanganate of potassium, with a saturated solution of oxalic acid, with a 1 to 1,000 solution of corrosive sublimate, and finally with absolute alcohol.

In Case II (Charity Club Hospital), under cocaine, bougies were passed into the ureters. This was done so that as much as possible of the base of the broad ligament could be removed without injuring the ureters. Unfortunately, carcinoma usually first extends outside the uterus at the junction of the cervix and the body just where we have but little room owing to the proximity of the ureters and bladder.

Many would think that this case was too far gone for a radical operation, but if there is even a ghost of a chance of giving even temporary relief, I believe in doing a suprapubic hysterectomy and removing just as much of the disease as possible. Your patient has a respite of a year or more without pain, and dies with less suffering and is less offensive and disgusting to herself and others.

Dr. Howard A. Kelly advises hysterectomy in all cases which have not passed beyond the limit of the palliative effect of the operation, even though there is no possibility of a cure, simply for the relief of the inevitable symptoms which must arise if the uterus is not removed.

In the *Johns Hopkins Hospital Bulletin* (July and August, 1895), Dr. J. G. Clark has an admirable article on "A More Radical Method of performing Hysterectomy for Cancer of the Uterus." I quote from him:

"For the radical cure of cancer of the uterus the same surgical rule obtains as in cancer of other regions, namely, total extirpation of the primary focus and as extensive areas of adjacent tissue as possible to insure the complete eradication of the disease.

"The faults common to all methods of removing the uterus are (1) the broad ligaments are cut too close to the uterus, and (2) too small portions of the vagina are removed.

"There are three essential steps in this operation which differ from those now employed: First, the introduction of bougies; second, the ligation of the upper portions of the broad ligaments, including the round ligaments and ovarian arteries, cutting them close to the pelvic walls, opening the two layers and dissecting the uterine artery out to its origin and ligating before exercising any tissue; and, third, the excision of a much larger portion of the vagina than usual."

In the *American Journal of Obstetrics and Diseases of Women and Children* (June, 1896), Dr. W. R. Pryor, of New York, in suggesting a more radical operation for malignant disease of the uterus where we have determined upon exsanguinating the uterus, bladder, vagina, deep iliac glands and obturator glands,

advises "the ligation of both internal iliac arteries." By these means he claims to be able to "make a bloodless dissection and more thoroughly than in any other way remove the disease." He advocates this method "in all cases of cervical cancer where the infection has extended to the pelvic glands, in all cases of recurrence after hysterectomy, and in so-called inoperable cases." He believes "this operation is perfectly justifiable, not as a curative procedure, but to lengthen life in a class of women who are doomed."

"After finding the bifurcation of the aorta, the finger runs down the right common iliac until its bifurcation is reached. The division of the common iliac is easily made out, and the examining finger is passed down the internal iliac artery for one inch. A careful search is now made for the ureter, which can usually be seen as a line of fibres beneath and somewhat paler than the peritoneum. It can be made to stand up prominently by gentle pressure for a space across the internal iliac artery, the finger crossing the ureter and constricting it, thus causing it to fill with urine.

"Having determined the location of the ureter, the peritoneum just at its side is picked up and nicked with scissors. Further dissection about the artery is done with the aneurism needle, which is gently worked around the vessel from above downward, the ureter being held aside.

"The ligature is then drawn under the artery and tied only tightly enough to occlude the vessel but not to rupture its coats. The peritoneum is now stitched over the ligature. Upon the left side the procedure is the same, only the rectum will have to be drawn to the right. The ovarian arteries are next tied close to the pelvic brim."

This is a bold procedure. Cleaning out the pelvis takes a long time, and some sloughing is liable to follow; but I believe time will show that it is, under certain conditions, the proper step.

In Case XI (Charity Club Hospital), the uterus, which a year previously had been ventro-fixed, silk having been used, was found suspended by a piece of omentum the size of a pen-stock — one end being attached to the parietal peritoneum at the point of fixation and the other to the fundus of the uterus. No silk could be found in either the abdominal wall or the fundus of the uterus.

At the present time, except in those cases where the question of future child-bearing is eliminated, the weight of opinion seems to be in favor of suspensio-uteri, as first done by Dr. H. A. Kelly, of Baltimore, ventral-fixation like vaginal-fixation having been condemned. I wish I were able, as Dr. T. A. Emmet says he is, to cure all these cases of retro-displacement by local treatment, mechanical appliances, and plastic surgery.

Case I (St. Elizabeth's Hospital) was a characteristic hospital case. She had had three attacks of pelvic peritonitis, morphine and poultices having been used to keep her comfortable until nature buried the seat of the disease with exudate and adhesions. When the patient or her friends get tired of this sort of thing, or an attack comes that is unusually severe, they discharge the attending physician or demand a consultation. We get the patient more or less septic, with the pelvic organs matted together, with the pelvic cavity shut off by adherent intestines, with ovaries converted into abscesses and often with large intra-extra peritoneal abscesses both in and out of the pelvis. If the

patient survives the sepsis and the operation, it is all right. It is no more than was expected of us.

Where the tubes and broad ligaments are the seat of tubercular disease, the uterus ought to be removed, as it is almost always infected; but in most of the tubercular cases I have had it was such a long, tedious, difficult operation to get out the tubes and ovaries that the uterus was left.

In two cases where it did not seem safe to remove the uterus at the first operation, a vaginal hysterectomy was done some months afterwards.

In one of the cases the uterus was shelled out through the vagina without clamping a vessel except two vaginal arteries.

In Cases IX and XVI (St. Elizabeth's Hospital), Dr. J. M. Baldy's operation for complete prolapse was done. The uterus had been outside the body for years, and was excoriated from chafing. Locomotion was difficult and painful.

Emmet's operation for cystocele was done at the same sitting with Dr. Baldy's operation. Then some weeks after Dr. Baldy's operation, the rectocele and ruptured perineum were attended to. The operation as devised by him is done as follows:

"The procedure is in all essentials a hysterectomy by amputation at or below the internal os. The points to be observed are: to include both the ovarian arteries and the round ligaments in the first ligature on each side of the uterus. To place this ligature as near the pelvic wall as possible, so as to leave but a small amount of broad ligament behind with the stump. To place but one other ligature on each side of the uterus, this ligature to include the uterine artery with as little other tissue as possible. This leaves both ligaments open. To amputate the uterus as low down on the cervix as possible.

"It will further be noted that the sutures include the sides of the cervical stump. It can readily be seen that the effect of tying these sutures is to lift up the stump of the cervix together with the vagina, and to bring it in close approximation with the ovarian stumps, doubling the opened broad ligaments together. Adhesions take place throughout the full extent of the double broad ligaments, and most surprisingly firm support is given from above to the vagina.

"The results accomplished are: The weight of the heavy uterus is removed, the over-stretched vagina is lifted high up and held firmly in place. The supports utilized are the natural supports of the uterus and upper portion of the vagina—the broad ligaments. The cervix remains a pelvic organ, as is natural to it.

"The plastic operations on the vagina I should judge to be absolutely essential as an adjunct to this as well as to any other similar procedure, for the reason that unless we remove the causes which produced the vaginal prolapse, we can hardly hope to escape a relapse, however well the work above may be conceived and executed. The class of cases to which this method is applicable is of course limited to those women in whom the question of future child-bearing is eliminated."

Dr. Baldy has performed the operation four times.

In Case I (Carney Hospital) after removing a hemi-atoma the size of a cherry, with all diseased tissue from the right ovary, the remainder was left, the edges of the ovarian tissue being fastened together with fine catgut. The retention cysts in the other ovary were punctured.

The condition found in Case III (Carney Hospital) was interesting. Adhesions were found between the intestines up above the lower border of the liver, with no history of an attack of peritonitis. I think the condition was due to tubercle bacilli.

In Case IV (Carney Hospital) we had an excellent chance to see how the pelvis looks some months after a hysterectomy. In this case there were no adhesions. Everything was smooth, and there was no evidence by feel or sight of any return of malignant disease. The base of the bladder was especially examined.

Case VI (Carney Hospital) helps confirm the rule that a pregnancy in the outer third of the tube usually terminates in abortion, and a pregnancy in the inner third nearly always terminates in rupture. The rupture in this case was one inch from the uterus.

Dr. J. M. Baldy estimated that in Philadelphia 1,500 women had lost their lives on account of undiagnosed extra-uterine pregnancy.

All have heard of the English actress who dropped dead in the Paris café.

Two years ago, in a small village within thirty miles of Boston, a farmer's wife, a strong, apparently healthy woman, was seized with severe pain in the abdomen about noon-time. Operation was refused at 3 P. M., and she was dead at 6 P. M. On opening the abdomen, post-mortem, two quarts of blood were found.

To my knowledge, two women here in Boston have died within the past six months from the effects of hemorrhage from a ruptured tubal pregnancy. Both refused operation until it was too late. One died within fourteen hours, and the other lingered along for six days, after the rupture. The abdomen was opened in both cases; consequently the diagnosis was verified.

There seems to be a difference of opinion just when to operate in this class of cases. No surgeon should operate on a moribund patient. Do not wait for recurrence of hemorrhage, but wait until the patient is in a condition to satisfactorily undergo an operation. Then do not delay.

I have seen strychnia and a normal salt solution bring back a pulse that had gone at the wrist; and very soon it was 120, and of good strength, and we were able to open the abdomen.

Certain collected 249 cases, and found, of the 173 operated, 21.3 per cent. died; of 76 treated conservatively, 85.8 per cent. died.

Martin collected 914 cases. Of these, 278 were treated conservatively; 33 per cent. recovered, 67 per cent. died. Of the 636 cases operated on, 80 per cent. recovered, 20 per cent. died.

The shock in these cases is produced both by the loss of blood and by the presence of free blood in the peritoneal cavity. All blood should be carefully removed from the peritoneal cavity as far as safety and time will permit, as blood after being in contact with the air is no longer sterile.

In Case VII (Carney Hospital) a portion of one tube was left. In July, 1895, a left tube and ovary were removed for ruptured extra-uterine pregnancy. The fimbriated end of the right tube was adherent. The adhesions were separated, and that patient was confined August, 1896.

If the condition of the tube will allow of its being left, I believe in dissecting out all diseased ovarian tissue and leaving the healthy portions. By leaving a portion of healthy ovarian tissue, menstruation continues, and this is a safety valve for most women. The

menopause is not precipitated and the change of life is more natural and less exhausting. The younger the patient, the more desirable I think it is to preserve menstruation.

A CASE OF "IMPERATIVE IDEA" OR "HOMICIDAL IMPULSE" IN A NEURASTHENIC WITHOUT HEREDITARY TAINT.¹

BY MORTON PRINCE, M.D., BOSTON,
Clinical Instructor in Nervous Diseases, Harvard Medical School.

MENTAL obsessions, in persons otherwise sane, are well known to alienists, but I think the general practitioner, who is less familiar with this psychosis, will find the following case of interest, not only in itself, but as throwing an insight into the mental condition of criminals who have committed homicides without apparent motive. When some horrible murder has been committed under the influence of an obsession it is necessarily often not possible to learn from the accused the motive, or, perhaps more correctly, the antecedent psychical state which leads to the act; but by a study of milder forms of homicidal impulse which have been successfully resisted, we can learn to understand the meaning of the severer forms.

It is difficult for a layman to realize that a momentary irresistible homicidal impulse may suddenly arise in an otherwise sane person, without warning, out of a clear sky, without motive and even against the afflicted individual's inclinations and feelings, and then cease for the time being, leaving the person in a mentally normal condition until another paroxysm occurs. But to the alienist this is A B C knowledge. This fact is illustrated by the following case:

Miss A. B., forty-two years old; dressmaker. With the exception of some sort of dizzy spells, which will be mentioned later, she always enjoyed good, robust health up to last May. At that time she was subjected to considerable anxiety and mental strain at the time of the confinement of her sister, whose life was considered in danger. She helped hold her sister while being etherized and during the instrumental delivery. She seems to think this ordeal affected her health, for after this, her head felt hot and tired, and she felt generally tired all the time. This neurasthenic condition continued without other symptoms until July, when she gave up work and her present psychosis developed.

She has had a general supervision and care of the child since its birth. Her psychosis consists, or has consisted, for she is much better at present, of an *overwhelming fear* that she would kill the child, and an *impulse* to do this. Against this impulse she is obliged to use self-control and resistance. The way this comes on is interesting and instructive. The fear and impulse are not continuous, but come on paroxysmally without warning, at unexpected moments. When asked to give an example, she said, in substance, of the last attack: "I was walking across the entry when I suddenly felt a queer feeling, which is not a pain, in my head, here and here and here" (indicating the occipital, frontal and parietal regions). This feeling she describes as a "sudden stoppage," as if she "couldn't think any further." With this feeling comes, of a sudden, the fear (that she will kill the child) and

the impulse to *do*. As will appear she has other impulses besides the homicidal one.

Besides the pain in the head she has had a pain in the left side which has preceded or accompanied the fear and impulse, but is present at other times. These organic feelings seem to constitute a sort of aura.

This attack is of very short duration. It may be only momentary, and I should judge never lasts more than a few minutes. Sometimes she has even awakened at night out of a sound sleep with this fear. The intensity of the fear and impulse may be judged from the fact that she has never been willing to be left alone in the house with the baby (she objected to her sister coming to see me, as that would require her staying alone at home to look after the child), and that on her first visit she was very much alarmed at her condition, thought she was "going crazy," and was troubled and mortified that she should have such thoughts. Still, she has never doubted that she could control the impulse, but the fear has been a cause of great mental discomfort. She has always insisted that she would not yield to the impulse notwithstanding the effort required to control it. The thought that she should have such feelings has been very distressing, so that she dislikes to talk about them.

The mode in which she would kill the child has taken different forms, apparently according to the surrounding circumstances. Sometimes the impulse has been to kill it with a knife; at other times, when looking out of a high window, to throw it out; and again to throw it upon rocks and stones when these have been obtrusive by the wayside.

This homicidal fear, which arose in connection with a particular child, was afterwards associated with other children. When, for example, she made a visit, largely for her health, to a relative in a neighboring State, she found that she suffered from the same feelings when she was with this relative's children. She has never had the fear of killing herself or grown people. In seeking for the origin of this fear, the first exciting suggestion of the mental state, it would seem that it might with considerable probability be found in the following circumstance, if the patient's memory is to be trusted: She has had the responsibility of the care of the baby. One day, while carrying it, she stubbed her toe and nearly fell. At once a fear rushed through her mind of the terrible consequences that might have ensued if she had fallen and killed the baby. The thought of this aroused its associated fear. From this time the fear that she might harm it, with the awful consequences, arose in her mind. Later this fear took definite shape or concrete form, in connection with definite modes of killing. The impulse would seem to be secondary to and a psychological consequence of the fear.

There remains to be mentioned another symptom, which I have purposely not mentioned, because although on first thought an important one, yet I conceive that in this case it is merely an accidental symptom and not an integral part of the psychosis. This is *hallucinations of sight* which arise at the time of the attacks of homicidal fear and impulse. The hallucinations vary according to the form which the impulse takes. When the impulse is to kill with a knife, she *sees* knives and blood about her; when the idea is to throw the child on stones, she sees stones. At one time she saw "brains and blood" constantly. These hallucinations have been very vivid and prominent.

¹ "One of them (the medical experts) doubted whether homicidal mania, so-called is a recognized disease." Editorial in Boston Transcript, on the Bram trial, January 4, 1897.

As hallucinations are not an element in this psychosis as ordinarily met with, at first sight it might appear that we had to do with some one of the delusional insanities, but on inquiry I was able to find a simple explanation of these hallucinations, of which the following would seem to be the mode of genesis. This patient has always had the power of visualization to an extreme degree. She says she has always had the power of seeing as a vivid image anything she chooses by thinking intently of it. She illustrates this in my presence, on my asking her to think of her breakfast table² as it appeared that morning. She says she sees as vividly as in a dream or as an hallucination the table, the things on the table and the faces of the persons around it.³ According to her statement, whenever her mind is occupied strongly with an idea of an object, she is apt to have a vivid visual image of that object. A constant panorama of objects has thus, especially since her illness, passed before her. She makes light of the images not connected with her impulses as being merely the consequences of a faculty which she has always possessed, but the homicidal images have troubled her. These, I take it, are nothing more or less than samples of this visualizing power, and awakened by the particular fear present, so that she sees as hallucinations or visual images the objects concerned with her fear. There have been no hallucinations of the other senses, nor any tendency to internal questionings and doubts,⁴ which last are frequently associated with fears and impulses. Beside this homicidal impulse this patient has exhibited others; for example, to throw anything that happens to be in her hand when the attack comes on; to rush out of a street-car, and to jump off a bridge.

During the past week (January 4th to 11th), she has been constantly annoyed by coprolalia, that is, an impulse to use profane language. This impulse seems to be confined to a repetition of the oath, "God-damn." This comes into her mind without external cause, and as she says is quite as likely to arise while she is saying her prayers as at any other time. It distresses her because she says she has never sworn in her life, and she "is not that kind of a person." She has resisted this impulse in that she does not say the words aloud, but they come into her mind all the time. She has occasionally since the onset of the psychosis had this impulse.

In character, unless I am mistaken, this patient is the last person who would by nature have such homicidal or profane ideas. She is fond of children, and children are fond of her. Her moral nature is strong, and her disposition is naturally kindly and amiable. A large part of her suffering comes from the consciousness that she has such horrid feelings so foreign to her disposition. She is proud of her will-power and refuses to allow herself to be governed by an idea.

When her trouble was explained to her, so far as this was possible, she exclaimed that if that was the case she would overcome these morbid feelings by her own will-power, and would not be beaten by her "imagination," and she would do this without treatment. (For this reason it is difficult to keep her

under observation.) To overcome the fear of jumping off the bridge, she deliberately walked to the open draw and stood there while it was open. This she says cured that fear. She has frequently, when the fear of homicide was upon her, deliberately taken up the child and fondled it to overcome the feeling. At other times, I think especially at the beginning of the psychosis, the impulse has been too strong for this, and she admits having to use great self-control to restrain herself.

No evidences of hereditary taint are discoverable. Her father is said to have died of phthisis when she was fifteen years old. She is proud of the fact that all the members of her mother's and father's family were strong, sturdy characters, and insists that no member of either branch ever had any nervous disease, or was addicted to excesses; but I have no reliable information further back than the immediately preceding generation. She has five brothers and three sisters, all strong and well.

Patient is well developed and nourished, and muscularly strong. The only physical abnormalities discoverable are an internal strabismus of left eye, dating from childhood, old choroiditis of the same eye, absence of lobes to the ears. These can scarcely be regarded as degenerative stigmata.

She is at present moderately "neurasthenic," that is to say, suffers from various sensory disturbances, "nervousness" and exhaustion. Talking about herself brings on the two last, so that she objects to being interrogated. She exhibits also a sort of impulsive lack of self-restraint difficult to describe, but which gives the impression that she resents and is irritated by being questioned, but she denies this, excusing herself by saying that the examination makes her feel worse. With the exception of having frequently suffered in the past from pain in her head, she was perfectly well up to three years ago, when for three weeks she had dizzy spells. In these she used to fall down and be very sick at her stomach; at the same time she had an intense painful desire to micturate. No auditory or other symptoms. These attacks would last not over one hour. Recovered perfectly. Only change in herself since has been that she cries more easily over what she reads or hears, and she is not so ambitious; otherwise she was perfectly well up to onset of present illness last May.

The patient has shown marked improvement under treatment (mental therapeutics, electricity and forced feeding).

Clinical Department.

A CASE OF CANCEROUS DEGENERATION OF A LARYNGEAL PAPILLOMA FOLLOWING OPERATION.

BY J. L. GOODALE, A.M., M.D.,

Assistant Physician to the Clinic for Diseases of the Throat in the Massachusetts General Hospital, Boston.

A. P., MALE, sixty-four years of age, with negative family and previous history, came in March, 1894, to the Throat Clinic in the Massachusetts General Hospital, in the service of Dr. J. Payson Clark, complaining of hoarseness of seven months' duration. Examination showed a pea-sized, sessile papillomatous growth situated on the free margin of the left vocal cord at the junction of the anterior and middle thirds.

² It will be remembered that Galton showed that this power of visualization was possessed by different people in varying degree. In some people it is normally highly developed, as in this patient.

³ It is interesting to note that the visual image was more vivid when her eyes were open than when shut.

⁴ Muckle has called attention to the three D's—Doubts, Dreads (fears), Deeds (impulses), as the three factors in this psychosis.

The tumor was removed by Dr. Clark and examined microscopically by the hospital pathologist, Dr. W. F. Whitney, who pronounced it a benign growth, being "a small vascular and fibrous mass covered by flat epithelial cells."

After the operation the patient escaped observation until April 22, 1895, when he returned to the clinic and stated that his hoarseness had persisted more or less but did not become marked until February, 1895, since which time it had rapidly increased. Examination showed the left cord and ventricular band transformed into a prominent, somewhat oval, reddened, roughly granular, rigid mass, encroaching on the lumen of the glottis, slightly moving on phonation. Right cord replaced by bright red granulations.

The larynx was excised *in toto* by Dr. M. H. Richardson. When laid open, it showed no extension of the disease below the cords or above the ventricular bands. Report of the pathologist, epidermoid cancer.

The patient died a week later from pneumonia.

I am indebted to Dr. Clark for kind permission to record the case.

RUPTURED OVARIAN CYST: OPERATION, RECOVERY.

BY J. ARTHUR GAGE, A.M., M.D., LOWELL.

Miss M., twenty-two, single, was at St. John's Hospital for operation on an ovarian cyst. At nine o'clock in the morning, after sitting up in bed, the cyst ruptured, and patient was found in collapse. This occurred during my absence from the city, and the operation was delayed till 3 P. M.

The abdomen was filled with the greenish, foul-smelling contents of a dermoid cyst that had escaped through a small opening in a necrotic area on the upper convexity above the umbilicus. The sac was removed, and contents washed out. The peritoneum was injected, and coils of intestine slightly adherent. All pockets were thoroughly cleaned, and six long strips of gauze carried among the intestinal folds to dependent parts and brought out of wound. It was necessary to inject one pint of salt solution into a vein to keep patient alive on the table.

The recovery was slow but complete, and wound has healed.

Medical Progress.

REPORT ON RECENT PROGRESS IN GENITO-URINARY SURGERY.

BY F. S. WATSON, M.D.

THE IMPORTANCE OF BIMANUAL EXAMINATION OF URINARY BLADDER IN DIAGNOSING HEMATURIA OF VESICAL FROM THAT OF RENAL ORIGIN.

MR. HENRY MORRIS¹ calls attention to the above subject, especially in cases in which examination by the cystoscope is rendered difficult, or becomes useless on account of easily excited and free hemorrhage from tumors of the bladder; and he reports three cases illustrative of its advantages.

If the patient be anesthetized, and bimanual examination practised by inserting one finger into the rectum or vagina, and exerting deep pressure downward upon

the abdominal wall above the symphysis pubis, malignant, and often, also, benign growths of the bladder can be detected and located.

SERO-THERAPIE DE L'INFECTION URINAIRE.

Under this title Albarran and Mossy² give a preliminary report of the results of their experiments to secure immunization against urinary infection which they consider to be due to the bacillus coli.

In the October number of the same journal is published a further report on the subject, which they presented at the Medical Congress at Nancy, August 6, 1896. The methods employed were by repeated inoculation with living cultures, or with maceration filtrates from the organs of animals which had died from the bacillus coli infection, or finally by alternate inoculations of these two of various animals, which had already been inoculated with bacillus coli.

Both prophylactic and curative results were successful with guinea-pigs, rabbits and dogs. Three months ago the writers made application of the treatment to the human subject.

This was practised by subcutaneous injection, and by injections into the bladder of a certain quantity of the serum; the results were favorable, and are to be reported in detail later by Professor Guyon.

They consider that this sero-therapy in the future will probably secure prophylaxis as well as successfully combat infection which has already developed, and may perhaps be used with advantage in connection with operations upon the genito-urinary organs.

REPORT OF SIX CASES OF BLADDER TUMOR.

Karstrom³ reports six cases of bladder tumor, in connection with which the following is a summary of the more interesting points:

(1) Fibromyoma of the urinary bladder. The patient was a woman fifty years of age. For a year has had frequent urination, and a feeling as of a foreign body in the bladder. During the first six months there was no pain or bleeding; after this time, however, pain gradually appeared, and hematuria soon followed. The urine became foul. The quantity of blood increased later, and finally became very large, the bleeding occurred as much when the patient was at rest as when moving about. Neither sand, calculi, nor bits of the tumor were ever found in the urine. An ill-defined tumor could be felt *per vaginam*. By digital examination of the bladder through the urethra a somewhat pedunculated tumor, about the size of a hen's egg, could be felt on the posterior wall.

Operation: Suprapubic cystotomy. A galvano-cautery snare was passed through the urethra, the base of the tumor surrounded by it, and the growth was removed almost bloodlessly. A second tumor, the size of a cherry, was found after the wound of the first operation had cicatrized, and was removed in the same way. The patient made an uninterrupted recovery. Microscopically the growth proved to be a fibromyoma.

(2) Alveolar myosarcoma. A man seventy years of age. Duration of symptoms two years. Passed bloody urine twice at the beginning. Painful urination soon followed, but there was no return of hematuria for nearly two years. Profuse bleeding then occurred. A tumor the size of an English walnut was felt by bimanual examination on the left side of the bladder just

¹ Lancet, October 31, 1896, p. 1210.

² Ann. des Mal. des Org. Gen. Urin., Mai, 1896.

³ Centralblatt für Chirurgie, November 7, 1896, No. 45.

above the prostate. The introduction of a sound brought about severe bleeding and suppurative cystitis.

Operation: Suprapubic cystomy. Rectal colpeurynter and Trendelenburg position. Bladder emptied of clots previously with Bigelow's evacuator. The growth, which had a broad base, was situated near the mouth of the left ureter. The growth was removed bloodlessly by a galvano-cautery snare. Bladder tamponed, and drained. Patient did well for some days, then acute infection of the pelvis of the kidney took place; from which he died.

Microscopical examination showed the growth to be as described by the heading.

(3) Papillomatous carcinoma. A woman of sixty-three years. Symptoms began three years ago. Painful urination, and from time to time hematuria, and occasional retention from large clots. Purulent cystitis. A portion of the growth only was removed, owing to the great extent of the bladder involved by it. It proved to be carcinoma with a papillary surface.

(4) Benign papilloma. A man sixty-five years of age. Symptoms began four years ago. There has been occasional hematuria since then; painful and frequent urination absent. No tumor elements were found in the urine. Tumor could not be found bimanually. Tumor was easily recognized by the cystoscope. It was situated near the orifice of the left ureter, and had a broad base.

The growth was removed by the suprapubic operation, with a galvano-cautery snare. Severe bleeding followed, which was stopped by cauterization of the site occupied by the tumor; bladder wound partly united by sutures and drained. Recovery.

(5) Benign papilloma. A man seventy-seven years old. Duration of symptoms four years. For six weeks vesical tenesmus; latterly hematuria; finally urinary retention. A large, lobulated tumor in the trigonum was easily seen by the cystoscope.

Suprapubic cystotomy. The tumor had a broad base. It was divided into two parts, each of which was tied off and then divided with scissors. The bladder drained after partial suture of the wound. Recovery.

(6) Carcinoma. A woman sixty-seven years old. For six months has had frequent and painful urination, and blood in the last part of the stream. A tumor was easily felt bimanually. Suprapubic cystotomy. A soft, friable growth. It was removed, together with the part of the bladder wall from which it grew, by an elliptical incision, the bladder wound being closed at once. The cystotomy wound was partially sutured, and drained. Uneventful convalescence.

THE INCREASE IN SIZE OF THE KIDNEY, AND POLYURIA IN THE ATTACKS OF INTERMITTENT HYDRONEPHROSIS.

Albarran⁴ begins a short but very interesting article by stating, as the accepted doctrine with regard to the series of phenomena occurring in connection with attacks of intermittent hydronephrosis, to be as follows, in the order of their occurrence: An obstacle to the outflow of the urine from the kidney; the accumulation of the urine in the renal pelvis; distention of the pelvis and the kidney due to this accumulation; the attack of pain; finally, the evacuation of the urine and the cessation of the pain. It is the retained urine that

causes the enlargement of the pelvis and of the kidney; and it is the sudden liberation of the urine which has been stored up in the pelvis which causes the polyuria.

Albarran believes, contrary to the above, that, in the early stages, at any rate, of the disease, the increase in the size of the kidney is due chiefly to congestion of the organ, and not to the retention of urine in its pelvis. In support of this view he adduces the following observations:

Complete retention of urine in the bladder causes an increase in the size of the kidneys by one-third of its volume. When this retention is continued, it causes interstitial ecchymoses in the parenchyma of the kidney, and may go so far as the formation of blood-clots in the pelvis. With complete ligature of the ureter there is great increase in the size of the kidney during the first hours, without any considerable collection of urine in the pelvis.

For clinical evidence Albarran reports an operation upon a patient who had had intermittent hydronephrosis for four years, during the attacks of which there was marked increase in the size of the kidney, and polyuria followed them. There was no sign of dilatation of the pelvis, or the kidney at the operation. The same experience was repeated in three other cases. He has also observed two cases of intermittent hydronephrosis with movable kidney, in which there was hemorrhage in connection with the attacks of pain, and in which at the time of operation there was no dilatation due to pressure, indicating that it had been due previously to congestion. Albarran notes, in passing, the failure of any one hitherto to observe this form of hematuria in connection with mobile kidney.

The polyuria which is so commonly observed after an acute attack, he considers to be dependent upon excessive secretion of urine by the kidney, and not upon an accumulation of urine in the pelvis, in support of which he cites cases in which the polyuria was marked (to the extent of a litre and a half of urine in less than an hour) in which there was but slight increase in the size of the kidney, and in which at a later time operation showed that there was no dilatation of the kidney.

THE VALUE OF RESECTION OF THE VASA DEFERENTIA IN PROSTATIC HYPERTROPHY.

Carlier⁵ reports the results of five cases of prostatic hypertrophy in which he practised resection of both vasa deferentia, to the extent of eight centimetres, between two ligatures.

The shortest period since the operation in any case was six months. In none of them had there been any improvement of the dysuria, but the urine in three cases from being cloudy had become clear. The latter fact he attributed to rest in bed and hygienic measures, and not to the operation.

Bosquet⁶ reports one case in which he performed resection of the vasa deferentia, with exactly the opposite result. The patient was a man of seventy-seven years. Six months ago he had his first attack of threatened urinary retention, which has been repeated twice since; on the last occasion, ten days ago, actual retention took place. Since then he has been regularly catheterized, and has been unable to urinate spontaneously.

⁴ Ann. des Malad. des Orgs. Gen. Urin., Novembre, 1896, No. 11, p. 987.

⁵ Loc. cit., p. 1056.

⁶ Loc. cit., p. 1059.

On examination the prostate was found to be the size of a fetus head at term. Catheterization was extremely painful and difficult. Resection of the vasa differentia was performed on the 14th of April, 1896. On the third day afterward catheterization was easier, and the patient urinated voluntarily. On the fourth day a false passage was made by the passage of a sound by a student; a catheter was tied in and allowed to remain three days, at the end of which time the patient was again able to urinate spontaneously. At the end of a month voluntary micturition was performed satisfactorily, and the prostate had diminished two-thirds in size.

DISINSERTION OF THE RECTI MUSCLES IN SUPRAPUBIC CYSTOTOMY.

By this term Desnos⁷ means the dissection of the insertion of the recti muscles from the upper margin of the symphysis pubis, as a preliminary step to intra-vesical operations. He suggests it as a substitute for the transverse division of the recti, practised by Trendelenburg and others, because of the objections to the latter, which are the frequent failure of the wound to unite, and the consequent weakening of the abdominal wall. The operation is proposed for those cases especially in which it is important to have an unusually free approach to the bladder.

He describes his operation as follows: The usual longitudinal incision is made, but is prolonged below to within one centimetre of the penis. The incision is carried through the soft parts to the symphysis, the insertion of the recti muscles on either side, together with the periosteum, are then divided to the extent of one and a half centimetres, along the upper margin of the symphysis. The periosteum and the tendinous insertion of the muscles are then lifted from the anterior surface of the symphysis for the same distance as above mentioned, which, when they are drawn aside freely, exposes the anterior surface of the bladder. After intra-vesical operation has been finished, the muscular insertions and periosteum are drawn together again and united by two or three sutures. The operation has been successful with the author.

The last four articles were presented at the meeting of the French Urological Society, October, 1896.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION FOR OBSTETRICS AND DISEASES OF WOMEN.

C. H. HARE, M.D., SECRETARY.

REGULAR meeting Wednesday, October 28, 1896,
DR. GEO. H. WASHBURN in the chair.

DR. F. W. JOHNSON read a paper on

DEDUCTIONS FROM HOSPITAL WORK IN ABDOMINAL
SURGERY, WITH A REPORT OF FORTY-FIVE CASES.¹

DR. CUSHING: I have been very much interested in this paper. It is a valuable contribution. It is a little difficult to discuss it as it takes in so much—almost a treatise on gynecology. Considering some

questions as nearly as I remember in the order in which they were taken up, one of the most important was of the value of the Clark operation for cancer of the uterus in comparison with the older vaginal hysterectomy. I have seen some of these operations, and they impressed me as very severe, requiring a long time, a very long time; and as we know, the patient who has cancer of the uterus which has gone into the broad ligament is not usually able to stand a severe operation as well as a woman with fibroid or something of that kind. It is admitted, I believe, that in the cases in which the broad ligament is really invaded there is practically no chance but what the disease will come back. Now, it seems to me we have to consider, not only the patient herself, but the status of surgery and the possibility of getting other women to submit to operation at the proper time. I think it is better that one woman if her cancer has got into the broad ligament should be allowed to die, with the dictum that she ought to have applied earlier for advice, than that half-a-dozen others should be frightened out of operation from the fact that the one had died from operation, or having been through all that painful experience, was not at all relieved. I do not think I shall be accused of undue timidity or hesitation in operating, but I think there is that side of the question. It was well impressed on me by my preceptor, Dr. James R. Wood, in the old times, that we have to consider the effect on surgery and on the community as well as on the patient. I have not seen enough in this thorough so-called Clark operation to make me incline to substitute it for vaginal hysterectomy or to use it where the broad ligaments are invaded; nothing more can be said for it than for the Krasky operation of turning back the sacrum and getting at the uterus there.

In regard to the sterilization of catgut, I am very glad that Dr. Johnson has adopted this material for intra-abdominal work, has become converted to its use and advantage. I have used it for several years in that way, and in the past have had some experiences which have led me to think the catgut may have been the cause of infection, but I could not be sure. I have had a good deal to say here in the last ten years as to the best method of preventing sepsis. Gradually results have got better, until I have not had sepsis for a long while. Part of the improvement I attribute to the better preparation of catgut, part to the better ventilation, and the greatest part to the more thorough disinfection of my own hands. The first method I used for preparing catgut was by soaking it in various solutions, and chromicizing it, but I could not avoid the idea that the presence of the chromium in the catgut was in itself a source of irritation. The method I use now is something which I got from Zweifel in Leipzig in 1890, sterilizing each strand separately by heat in a tube. This method of the envelope is a beautiful one. I use a tube. The catgut is kept in ether so that it is thoroughly degreased, or whatever the proper word is, and cut into lengths, and each length put into a clean tube and baked for two hours at 140° C. It must be thoroughly dried first, for if there is any moisture in it it will spoil the catgut. If it is dry it tans it. I put it in 95-per-cent. alcohol with five-per-cent. glycerine. That soaks into the catgut and makes it supple enough for use. Paraffine paper seems to have the same effect and that is also an excellent way. One

¹ See page 52 of the Journal.

⁷ Loc. cit., p. 1069.

of the three things I have improved in getting rid of the sepsis is not having the catgut in a receptacle where it has to be used more than once. I used to have it in a jar, several strands together. The method of having each strand separate is the correct one. I have used catgut a good many years now and I fail to find any trouble within the last five years attributable to catgut. I use it for all intra-abdominal work without exception.

About the buried silver wire I fully appreciate the advantages, but still I have some doubts about leaving buried things in the body which are liable to give trouble at a subsequent day. Edebold was trying to convince us a few years ago that it was the proper thing to use buried silkworm-gut in the abdominal wall. Presently he came out with a paper and said that 10 per cent. of his cases finally suppurated. We may find the same thing with silver wire. Ten years ago I sutured a patella with silver wire and that has never given any trouble. Some time afterwards I sutured the ankle-joint and that did give trouble and finally the wire had to be removed. Some one told me of a case where a hernia came on after a wound was sewed in this way with a row of buried stitches and the hernia came on leaving all the sutures at the side; so that we cannot get perfect security even from that, although it is a most promising field if we can have something that guards against hernia.

I should only wish to make one suggestion, that I do not think vaginal fixation of the uterus should be thrown overboard so unceremoniously because some bad results have been reported. It has been used very extensively and a few cases have been reported where in subsequent pregnancy there was trouble in the development of the uterus, but I have found in a great many cases it was not necessary to do such a thorough operation as is done in Berlin, where the whole uterus is dragged out in front of the bladder and organic union between the decorticated anterior surface of the uterus and the fascia is made, so that the whole thing grows together as one solid mass. If the uterus is brought up and fastened without opening the peritoneum at all and the cervix fastened back, in a great many cases the malposition of the uterus will be relieved. I am speaking of retroversions and not of prolapse. In regard to Dr. Baldy's operation I do not see that it gives much greater suspension than vaginal hysterectomy where the broad ligaments are pulled down and fastened in the angles of the wound. If there is a prolapsed uterus and in removing that we bring the ligaments down we have the uterine artery tied off and the upper part of the broad ligament brought down, the uterus being removed, then these ligaments dip down and are fastened with sutures in each corner. The same effect can be got operating from above and leaving the cervix, by fastening the top of the broad ligament into the angle of the cervical stump. It is a question of preference which any one does. Some of these women who have prolapses are fat and it is a very bad place to make an abdominal incision. It is not comfortable to do hysterectomy from above, it is a long operation with somewhat more shock than operating from below.

DR. ENGELMANN: We are not as yet in a position to so completely discard vagino-fixation as Dr. Johnson would have us do: the operation has proven satisfactory as far as fixation of the organ is concerned, the

uterus is securely held in the position given, I may say more so than by any other method; but more than by other methods, as time has shown, is its functional activity interfered with—miscarriage and life-endangering labor have been too often observed as a sequence to vagino-fixation, and for this reason I would discard the operation for functionally active uteri during the childbearing age as is now generally conceded; but after the menopause it must be considered equally with other methods and in connection with vaginal salpingo-oöphorectomy I take it to be the method of choice. The resulting evils being due in a great measure, as Dr. Cushing has said, to the very unnecessary fixation of the entire corpus uteri to the vaginal wall. These may be to some extent avoided by attaching only the lower portion of the body; a certain mobility is thus retained. Other methods have their disadvantages as well. The functions are less liable to be interfered with, but fixation is also less firm, and one of the dangers attending ventro-fixation recently emphasized by Jacobs at the Geneva Congress, is the dragging down of the peritoneum by the constant traction of a heavy uterus until the organ is suspended from the abdominal wall by a thin band, like a pedunculated growth. Four such specimens were demonstrated, one with a suspensory band over four inches in length.

The shortened round ligaments, too, are likely to yield, so that, by reason of the firm fixation secured, vaginal hysteropexy with all its disadvantage must still be retained for the non-childbearing woman.

Dr. Johnson's method of catgut sterilization must yield good results, I am sure, but we have now a variety of procedures, all equally safe, if judiciously carried out and each operator will retain that method which has given him good results, which he has mastered and perfected. Even some of the older methods, if rightly applied, yielded a safe material, so I have for many years used the original Koehler method, even throughout that still comparatively recent period when catgut was decried and almost abandoned as unsafe and not with certainty sterilizable.

The sterilized gut, as obtainable in the market, was indeed unreliable, but that which I myself imported and prepared answered all requirements, this I attribute in the main to the time allowed, four months at least in the alcohol, glycerine, sublimate solution, with repeated changes of fluid. Later I boiled it in alcohol instead of leaving it for twelve hours in the stronger preparatory fluid before placing it in the permanent solution.

It is not so much the method, as the manner in which it is carried out, upon which we must rely for a safe and satisfactory material.

DR. CUMSTON: The question of catgut and absorbable ligatures is a very important one, and, had I known that the subject was to be introduced into the discussion, I would have brought some specimens of catgut prepared after my method. I wish it to be distinctly understood that the method of which I shall speak is only original with me, in this sense, that it is a combination of processes, and each process has been used by its author, but no one has combined them together in my manner.

While in Geneva this summer, I saw some catgut as used in Kocher's clinic, which can be boiled after first soaking it in a solution of formalin, which renders the catgut suitable for boiling. I carried out

some experiments in Geneva, and have worked on the question for some time since I have come home; and, after considerable time spent in this direction, I would formulate the following manner of preparing catgut, so as to render it absolutely sterile.

But, in the first place, I would insist on one very important point, and that is that the quality of the gut should be of the very finest. I think that in a great many cases the catgut which has been sterilized after the various methods advocated by authors and that employed at the Johns Hopkins Hospital, and in which a success has not been obtained, was not good.

I prepare it as follows: In the first place I came to the conclusion that in order to have a gut which can be properly sterilized, the fat must first be removed entirely. For this purpose I tried soaking it in ether, and found that at least twelve days were necessary in order to remove the fat completely, and that it was also necessary to change the ether three or four times during the time. I then discarded using ether, and I now employ a solution of one to two hundred solution of nitrate of silver, which was advocated by a Russian surgeon, whose name I do not now recollect, and I leave the gut in this solution for two hours. I found that the fat was sufficiently acted upon after it had been in this solution for two hours, as it became quite black in color, showing that it was thoroughly attacked by the nitrate of silver. The gut should then be washed for about three hours and then wound on spools, after which it is placed in a four-per-cent. solution of formalin, in which it is left for thirty-six hours. To make a solution of four per cent. you take one part of commercial formalin, which is a forty-per-cent. solution, and add nine parts of distilled water. After soaking in formalin for thirty-six hours, the gut is removed, placed in a basin, and washed for twenty-four hours in running water, after which it is removed and placed in a Schimmelbusch sterilizer and boiled for twenty minutes. The spools are then placed in a tube containing either an alcoholic solution of iodine, to which a little glycerine is added, or, as I prefer, the following: naphthol beta, one part; absolute alcohol, seventy parts; and glycerine, thirty parts.

If the catgut employed is of good quality, I fully believe that this method will render it perfectly sterile, because the boiling-point of water being higher than that of alcohol, the gut is submitted to a much higher temperature, and we all know that it is generally considered that any instrument or dressings which have been boiled for fifteen minutes, may be considered as surgically aseptic.

DR. JOHNSON: I think the operation for carcinoma by suprapubic hysterectomy has come to stay. At the Johns Hopkins Hospital they are having excellent results. They take out the uterus, both broad ligaments, and all the glands at the bifurcation of the iliac vessels, and, if necessary, remove one-half to two-thirds of the vagina all in one piece.

In 37 cases of cancer of the cervix, the results at the Johns Hopkins Hospital were as follows: 10 per cent. died from the immediate effects of the operation; 38 per cent. died with recurrence; five per cent. were not heard from; and 43.2 per cent. were still alive after a period of one to five years.

This is very good showing and it seems to me that this operation will be done more and more for carcinoma of the uterus.

In reference to the buried-wire sutures, the fascia is brought together in this way: A figure-of-eight suture is passed between the edges of the divided fascia every inch and a half. When the wires are drawn tight and twisted, the fascia is brought together in the median line, and firmly secured and protected by the silver sutures.

Each time I sterilize catgut I do not use it until each lot has been tested by the bacteriologist and I am told it is absolutely sterile.

In vaginal hysterectomy with suspension of the vagina by the infundibulo-pelvic ligaments for the cure of complete prolapse of the uterus, the vagina is not suspended so high or fastened so securely as in Dr. Baldy's operation. In Dr. Baldy's operation the ovarian arteries are tied as close to the pelvic wall as possible, and thus remain as fixed points to which the stump of cervix, with the attached vagina, is drawn up and fixed by heavy silk sutures.

NEW YORK NEUROLOGICAL SOCIETY.

STATED Meeting, November 5, 1896, DR. B. SACHS, President.

REVISION OF THE NEW LUNACY LAW.

The President appointed on the committee charged with this matter, the following: Drs. G. M. Hammond, C. W. Jacoby, N. Allen Starr, C. L. Dana, and Joseph Collins.

A CASE OF ACUTE MULTIPLE NEURITIS, OR ANTERIOR POLIOMYELITIS, WITH INVOLVEMENT OF THE FACE.

DR. L. STIEGLITZ presented a boy, six years of age, who had come to the clinic of Dr. Starr on October 13, 1896. He had been healthy up to September 28th, at which time the right side of the face was noticed to be paralyzed. Five days later, there was an attack of vomiting and high fever. On the second day of the illness, the power of the left arm was lost, and two days after this, the power of the right arm was also lost. Motion of the arms caused pain. At no time was there any trouble with micturition or defecation. There had been no sore throat previously, and no history of poisoning by alcohol, or by the metallic poisons. The boy was found to be very anemic and thin, and his temperature was normal. The pupils responded well to light and accommodation. There was no disturbance of vision or hearing. There was complete facial palsy of the right side of the face, but the left side was unimpaired. The tongue protruded without deviation. Electrical examination showed gradually diminished excitability of the right facial nerve to both currents. On the right side of the face there was partial reaction of degeneration. The sense of taste was unimpaired on both sides. There was complete reaction of degeneration of the paralyzed muscles of the right arm and shoulder. The left quadriceps femoris was found to be weaker than the right. None of the other muscles of either leg showed the least loss of power, and there was no disturbance of sensation throughout the body. The paralyzed muscles were tender on pressure. There had been a gradual recovery of the motor power in the affected muscles. On making the diagnosis one had to choose from three conditions, namely:

(1) acute infectious multiple neuritis, with involvement of the facial nerve; (2) acute anterior poliomyelitis, with involvement of the right facial nucleus; and (3) the ordinary Bell's palsy.

At first, he had been inclined to look upon the case as one of multiple neuritis, but the distribution of the paralysis did not accord at all with the symmetry considered to be characteristic of multiple neuritis. Again, the greatest paralysis was in the upper arm; the only muscle paralyzed in the lower extremity was one quadriceps femoris. The distribution of the paralysis seemed to be almost pathognomonic of infantile spinal paralysis. The only feature interfering with the classification of this case as one of anterior poliomyelitis was the presence of facial palsy. Such cases were decidedly rare, but they had been reported. The speaker concluded that his case was one of acute poliomyelitis, associated with a coincident Bell's palsy of the ordinary type.

DR. M. ALLEN STARR said that he had examined the case very carefully at the clinic, and coincided entirely with the diagnosis made by Dr. Stieglitz, that is, that there were present two independent affections.

DR. ^oTERRIBERRY said that the boy still complained of considerable pain when the right arm was moved. One would hardly expect to find such a sensory condition at this stage if the case was one of poliomyelitis. He inclined rather to the view that the case was one of multiple neuritis. Taking this view of the case, the face palsy would coincide with the rest of the condition.

DR. C. W. JACOBY said that the emphasis laid upon the sensory symptoms would certainly lead one to think that the neuritic symptoms preponderated; hence he saw no reason to classify the case in either one or the other category. The case corresponded very closely with those described as combined cases of poliomyelitis and neuritis.

DR. STARR said that in his experience pain was a common symptom of anterior poliomyelitis. In not a single febrile case, seen by him in the last four years, had pain been absent. We must, of course, separate the febrile from the afebrile cases. In the latter class the pain was not ordinarily present. He had now under his care a little girl who had the attack last August, and still she suffered a great deal of pain even at present. In this case the distribution of the paralysis was thoroughly characteristic of anterior poliomyelitis.

DR. EDWARD D. FISHER thought that the distinction should be made in the pain. The pain in the cases of neuritis was found especially along the course of the nerve, whereas the pain in the cases of poliomyelitis was more in the muscles, or upon movement of the muscles.

The PRESIDENT said that he had already published the statement that pain was a particularly significant symptom in the early stages of anterior poliomyelitis. Children in the early stages of this disease almost always show pain to a marked degree, and it was often very difficult in practice to make the distinction alluded to by the last speaker. He had now under his care a child who was exquisitely tender, although now in the sixth week of the disease. On the other hand, he believed that the two conditions might occur in the same patient, and he could see no absolute necessity for these strict clinical classifications in every case.

DR. STIEGLITZ said that the prognosis depended

very much upon the exact diagnosis, and hence, these distinctions were of practical importance. The case he had presented had no paresthesia, and the nerve trunks were no longer sensitive to pressure, although the muscles still exhibited some sensitiveness.

COMPRESSION OF SPINAL CORD BY A HYDATID CYST.

DR. PHILIP MEIROWITZ presented a man, fifty-seven years of age, suffering from compression of the spinal cord, or rather who was now in the post-compression stage. In 1882, he had a severe attack of inflammatory rheumatism, and it was nine months before he had been entirely well. From 1883 to 1887 the extremities were the seat of pain, apparently rheumatic in character. In 1889, a small tumor developed to the right of the lower part of the spine. In 1893, a second tumor appeared in the lower part of the right dorsal region, and shortly after this a third swelling made its appearance between these two. He subsequently developed weakness in the lower extremities, and difficulty in evacuating the bladder, but there had been no dribbling of urine. He experienced a sensation of coldness in the lower extremities, and on the body up to the umbilicus. The sexual functions had been gradually lost. On May 15, 1896, the examination showed a large swelling, consisting of three tumors in the lower part of the back, to the right of the vertebral column. This tumor was distinctly fluctuating. The man walked at this time with extreme difficulty. Sensation was diminished in certain areas, but in no place was it entirely lost. The patellar reflexes were markedly exaggerated. There was a diminution of electrical contractility in the muscles. A clear, colorless fluid was drawn off from the spinal tumor, and microscopical examination showed the hooklets of the echinococcus. Dr. Samuel Lloyd operated upon the case on June 13, 1896, with the most gratifying results. The speaker examined the man again on October 11th. At that time the paraplegia had entirely disappeared, and he was able to walk long distances without assistance. Tactile sensation was still slightly diminished. The functions of the bladder were much improved, as were also the sexual functions.

DR. S. LLOYD said that the tumor had extended from the middle of the scapula down across the sacrum. A tumor the size of a fetal head dipped in toward the abdomen on the right side. A point of interest in the case was the diagnosis. As the cyst was a multilocular one, he had not been able to accept the diagnosis that had been previously made of cysto-sarcoma, and owing to the localization of the metastases he had been led to doubt the diagnosis of multiple sarcomata. Another possible condition was a large hydro-nephrosis, but the diagnosis had been settled by microscopical examination. It was probable that the cyst had not originated in the spine, but had extended into the spine. The point of entrance of the tumor into the spine was between the laminae of the eighth and ninth vertebrae. This exactly corresponded with the localization made by Dr. Meirowitz. One old cyst and three smaller ones were removed from the cord at that point, but no effort was made to explore further on account of the already extensive operation demanded.

THE PATHOLOGY AND TREATMENT OF MIGRAINE.

DR. C. A. HERTER read a paper with this title. The treatment to be advocated, he said, was a depar-

ture from that usually followed, although not original with him. The typical migraine paroxysm seemed to be almost always associated with nutritive disturbances, which should be considered as part of the migraine paroxysm. Too much attention, he thought, had usually been given to the relief of the pain. There were many features in a typical attack of migraine indicating gastro-intestinal disturbance. During the period of marked headache there was usually no great evidence of intestinal derangement, although there was often at least slight constipation. The feces generally appeared normal. The urine passed during the period of marked headache was exceedingly scanty, high colored, of high specific gravity and acid. Apparently the quantity of uric acid was diminished, and the excretion of urea and the chlorides was regularly diminished, due chiefly to the temporary abstinence from food. The ingestion of food often caused severe nausea and vomiting, but sometimes it was significant that it caused a return of the hemicrania. There was a rapid transition from the period of diminished excretion to that of increased excretion — sometimes within twenty-four hours. Usually after a severe migraine paroxysm, the urine was increased in amount on the second and third days after the headache. The uric acid was increased and the extractives also. In seven different patients he had had an opportunity of examining the contents of the stomach in the paroxysm. In these cases there had been evidence of complete arrest of gastric digestion. In one case he had found considerable undigested food in the matter ejected from the stomach nearly nine hours after dinner. There was also evidence that not only the secretory but the motor activity of the stomach was diminished or temporarily arrested. It was probable that the secretory activity of the small intestine suffered in a similar manner.

The first step in the treatment of migraine seizure should be the washing out of the stomach with water at a temperature of not less than 105° F. The chief effect of this treatment is to relieve the pain, and it occasionally aborts the attack. The best results are obtained when the stomach washing is done just at the beginning of the attack of headache. The effect of lavage is better where the stomach contains food, but it should be employed in any case. Where lavage was inconvenient, the patient should drink hot water. While the results were marked and rapid, the *rationality* of the method was not so apparent. It was possible that in migraine the tolerance of the nervous system is suddenly exhausted, and hence the removal of a relatively small quantity of toxic material from the stomach may be sufficient to decidedly influence the attack. After the stomach washing, the patient should be given a rapid-acting cathartic. His observations would seem to show that in migraine intestinal putrefaction was not an important factor. It was desirable to avoid severe purgation on account of the undue irritation produced. The cathartic should be aided by a hot soap and water enema, and this should be given even though there had been a recent stool. If this active treatment were begun within the first hour of the headache, it not only markedly relieved the pain, but often cut short the paroxysm. When the headache returned, it was more easily treated after these initiative steps. Antipyrine he has found unreliable, and apt to cause severe digestive and vasomotor derangement. Phenacetin, in doses of ten

grains, repeated if necessary, was usually useful. Antifebrin, in doses of five grains, relieved the pain still better, but sometimes acted unpleasantly by depressing the heart. The best of all seemed to be ammonol. This was claimed to be a mixture of an ammonia salt with antifebrin. Black coffee, without sugar, he had found often very efficacious, and the same might be said of citrate of caffeine. Where the face was regularly much flushed, ergot sometimes acted well, but usually this preparation was not easily retained. He would not care to use nitro-glycerine except in cases in which there was distinct flushing of the face. Local applications could only be regarded as feeble adjuncts to the ordinary treatment. It was a pernicious practice to give one of the antipyretics mentioned, and not insist upon temporary rest and quiet.

The speaker said that although it might be safely assumed that there was a toxemia present in severe attacks of migraine, we must admit our utter ignorance of the nature of this toxemia. It was probable that in health the albumoses were absorbed only to a very slight extent. When introduced into the circulation in animals they were found to be much more toxic than peptone. In sufficiently large doses the albumoses were invariably fatal. It was possible that substances identical with, or closely allied to these substances formed from the digestive process, might be absorbed into the circulation without further change. It was possible that in migraine that there was absorption of pathological albumoses, more toxic than in health. The rapidity with which the headache might be produced in migraine by the ingestion of proteid food would seem to indicate that the attack was brought on by unorganized ferments rather than by bacteria. He could not believe, however, with Haig, that migraine was due to an excess of uric acid, or its salts in the blood. Rachford had claimed that migraine was due to poisoning with hypoxanthine, but so far his observations had not been confirmed by others, and they should therefore be considered only as highly suggestive. The theory of toxemia, however, did not explain the unilateral character of many of the symptoms of migraine, and some other phenomena. We must admit, as in epilepsy, that there was an inherited tendency in the nerve cells which rendered them excessively sensitive to the action of such poisons. To this must be added another important factor — fatigue. He was inclined to believe that the digestive derangements and the toxemia always preceded the headache, although doubtless at the height of the attack the nervous and digestive conditions reacted upon one another. In this connection, it should be mentioned that sexual excitement was often a marked exciting cause of migraine. In the intervals of the attack, the closest attention should be given to the nutritive disturbance present. Milk should constitute the proteid food of at least one meal a day, and red meat should not be allowed more than once a day. Many of these patients cannot tolerate fruits any more than gouty individuals. He had known a number of most intractable cases of migraine surprisingly improved by a change to out-door life. Horseback riding and bicycle riding he believed to be the best forms of exercise for these persons.

DR. M. ALLEN STARR expressed his hearty approval of the paper, and particularly of the therapeutic considerations embodied in it. During the past two

years he had given the Rachford method of treatment a careful trial in several cases of migraine. The results had been exceedingly good, even in some very obstinate cases in which all the recognized methods of treatment had proved of little value. He had found a few cases in which muriatic acid given at the time of the paroxysm, would arrest it. The "Rachford salt" consists of ten parts of phosphate of sodium, four parts of sulphate of sodium, and two parts of salicylate of sodium, of which one drachm was to be taken in the morning. As this dose was not sufficient to cause purgation, he hardly knew to what to ascribe the benefits derived from this treatment. Rachford had insisted upon the necessity of coating the pill of permanganate of potassium in such a manner as to have the pill remain undissolved until it reached the intestine. By means of keratin coating he had had capsules prepared, containing permanganate of potassium and salol. Regarding the diet, he said that it seemed to him very essential to restrict the quantity of red meat. He had found abdominal packs and abdominal massage quite useful in cases of migraine.

DR. MARY PUTNAM JACOBI said that a few months ago she had tried on a very severe case of migraine the washing out of the stomach, and had been able in that way to arrest an attack which was unusually severe. In this case, the stomach was entirely empty at the time of the washing. The relief was so marked that since then the patient had insisted upon washing out her stomach.

DR. FREDERICK PETERSON said he was inclined to accept the toxicemic theory of the origin of migraine. He had used the Rachford treatment in a number of cases, and had found it unusually successful. One or two patients had rebelled against the Rachford pills on account of the irritation they produced.

DR. L. STIEGLITZ said that he could not accept the view of the toxins giving rise to migraine coming from the alimentary canal. The periodical cases of migraine often vomited repeatedly, and yet the attack was unrelieved. The hypodermic injection of a small dose of morphine at the onset of the attack often aborted the attack, and as the morphine acted in the opposite way to the treatment advocated by Dr. Herter and Dr. Rachford, the theory did not seem sufficient to explain the phenomena observed. There seemed to him to be a very close connection between epilepsy and migraine. One patient, in his practice, had attacks of migraine every eighteen days; it was difficult to believe that the alimentary canal became disturbed and gave rise to toxemia so regularly.

DR. JOSEPH COLLINS said that in a recent case, that of a woman of thirty-five or forty years, the complaint was of an acidity or soreness in the entire alimentary canal, and of unpleasant sensations connected with micturition and defecation. The paper just presented was exceedingly instructive, as it described most clearly certain clinical features not often emphasized in the text-books. He felt with the last speaker that there was a very close genetic connection between migraine and epilepsy. The speculations on the action of the albumoses did not seem to coincide with the treatment advocated in the paper, and also by Dr. Rachford. He had tried the Rachford treatment quite faithfully for two years, but had been unable to find it any more beneficial than the other methods of treatment. He would also say that he had not found ammonol of any use whatever. He had obtained good

results, however, from a combination of fifteen grains of phenacetin, ten grains of salicylate of sodium and five grains of salicylate of caffeine. He had also found a combination of tincture of gelsemium, tincture of belladonna and acetate of potassium very useful in migraine, especially in cases in which the bladder symptoms mentioned were present.

DR. CHARLES H. BROWN said that he had seen a dose of twelve grains of ammonol in one case cause extreme and dangerous prostration, and he had not observed any benefit from its use in other cases. In the patient referred to, there had been no unpleasant effects observed from the use of antipyrine, antifebrin and phenacetin. In many cases of migraine the polyuria preceded the headache by twenty-four or forty-eight hours, from which it would appear that there was something else besides the toxemia in the etiology of migraine.

DR. WILLIAM HIRSCH said that the chief objection to the toxemia theory of migraine was the occurrence of unilateral symptoms, and the fact that one side of the body alone would be affected time and again. He recalled a case in which a temporary hemiplegia during migraine had finally become permanent hemiplegia. This could only be explained by repeated vaso-motor spasms, leading to a permanent change in the cortex. At the present time, he had under observation a lady who suffered from migraine at each menstrual epoch. The case had proved very obstinate to all the usual methods of treatment, but had yielded best to treatment during the intervals, with large doses of the bromides — just as one would treat a case of epilepsy.

DR. HERTER, in closing the discussion, said that notwithstanding the criticisms that had been made of his treatment, he had the greatest confidence in it, for although ordinarily not very sanguine in therapeutics, he had seen the most gratifying results from its employment. Of course, the patient must be taught to wash out the stomach and attend to the other measures promptly without waiting for the arrival of the physician. As a rule, patients did not vomit until the paroxysm had been well established, and absorption was probably going on through a large extent of the intestine, and hence, it was not surprising that the eliminative treatment advocated by him did not accomplish much when employed so late. Many of his medical friends had agreed with him that ammonol was a most useful drug for relieving pain, and he had not heard of any unpleasant effects from its use. He believed that toxemias gave rise to hemiplegia much more commonly than was usually supposed; hence this would explain Dr. Hirsch's case. It was the rule for polyuria not to appear until the headache had passed, although occasionally it would persist for a number of weeks.

THE mortal remains of Louis Pasteur, which have lain in the cathedral of Notre Dame since the funeral a year ago, were removed to their final resting-place at the Pasteur Institute, December 26th.

CONGENITAL ABSENCE OF BOTH PATELLÆ. — Bristow, of Brooklyn, in the *Medical News* of January 24, reports a case of this curious condition occurring in a child of two and one-half years, the subject of double pes varus. Skiagraphs of the knees taken from the front and side give an excellent illustration of the deformity.

Recent Literature.

Modern Greek Mastery, A Short Road to Ancient Greek. By THOMAS L. STEDMAN, A.M., M.D. New York: Harper & Brothers. 1896.

The chief aim of this little book is, as the title states, to teach Greek as a living language. The author in his preface deplores the unnecessary time spent in acquiring ancient Greek by the time-honored method of minutely mastering the intricacies of the grammar before the language itself has any meaning to the student. He points out that a knowledge of modern English is necessary to a satisfactory understanding of Chaucer and the early English writers, and that modern and ancient Greek are even more closely similar than modern and ancient English. Incidentally the literature of modern Greek will well repay the student, and in travelling in the Orient and Eastern Mediterranean countries, a knowledge of modern Greek will be of the greatest value. He considers that the adoption of modern Greek as a language for international congresses is the best solution for the difficulties which are due to the polyglot character of these assemblages.

With regard to the first contention that the best road to a working knowledge of a language is through actual use and conversation, there can be no doubt that it is true. A residence in a country where the language is spoken is admitted to be the quickest method of acquiring a practical and idiomatic use of that language. The lack of this actual residence and daily use is what this little book aims to supply, and doubtless does in some degree. If the book conscientiously studied will give a working knowledge of modern Greek, it will certainly be far easier for the student to master ancient Greek, and his knowledge of the latter will be of the living and conversational, rather than the dead and grammatical, sort.

The book seems a step in the right direction in the teaching of the classics. The advisability of the adoption of modern Greek as a language for international congresses, however, admits of question.

A Treatise on Obstetrics. For Students and Practitioners. By EDWARD P. DAVIS, A.M., M.D., Professor of Obstetrics and Diseases of Infancy in the Philadelphia Polyclinic, Clinical Professor of Obstetrics in the Jefferson Medical College of Philadelphia. In one very handsome octavo volume of about 600 pages, with 217 engravings and 30 full-page plates in colors and monochrome. Philadelphia and New York: Lea Brothers & Co. 1896.

The modern character of this work is shown by the large number of original photographs, including several skiagraphs. The Röntgen rays have, however, added nothing as yet to our obstetrical knowledge.

There is much to be learned from the actual photographs of normal and abnormal deliveries, but one is rather surprised to see a child delivered by the breech by an attendant with arms covered with shirt sleeves.

On page 225 there is a confusing picture, apparently from a photograph, entitled "Bringing the head upon the pelvic floor, normal breech labor." Here, judging from the way the feet point, the back is uppermost, as is proper; yet the infant is possessed of groins and penis on this upper surface.

Some of the other photographs are decidedly con-

fusing, and those showing the application of the forceps contain a surprising number of hands in a small space, nine appearing in Fig. 163.

The photographs are all characterized by great modesty, thus distinguishing them from other recent obstetric photographs, the faces being all draped, except in the case of one negro patient. The abdomen as well as the face is covered with a sheet in those showing palpation, the result being quite obscure.

The arrangement of the chapters and subjects is at times perplexing. Turning to Eclampsia, we find only four and a half pages on this interesting subject, but concealed under the heading of Toxemia of Pregnancy, in another part of the book, some fourteen pages of great interest are added to this subject. In the same way various forceps operations are described and figured in the first section, together with a brief description of version. In the second section forceps operations in abnormal pelves are described, but in the third section we find all the operations described and figured in detail.

There seems to be no account of the symptoms and management of hydatidiform mole.

Symphysiotomy is carefully described, and the author asserts that where this operation is properly performed under antiseptic precautions, the symphysis unites firmly and well.

Rather more space is given to the diseases of infancy than is usual in obstetric works, although these sections are far from complete. Under Rickets one is surprised to find the statement that if the mother is rachitic it is reasonable to suppose the child will also share her malady, and a large fetal head is therefore expected.

Section seven is on the "Jurisprudence of Obstetrics."

Aside from these criticisms the work is one of practical value and interest to students and practitioners alike.

Essentials of Physical Diagnosis of the Thorax. By ARTHUR M. CORWIN, A.M., M.D. Second edition, revised and enlarged. Philadelphia: W. B. Saunders. 1896.

The popularity of Dr. Corwin's little book is shown by the appearance of a second edition, which has been enlarged by the addition of a section setting forth the signs found in each disease of the chest. The criticism which was made in these columns on the previous edition is equally applicable to this, that the method of instruction which it pursues is faulty in that it appeals to the memory of the student rather than to his reason by presenting a series of apparently independent facts instead of showing the logical connection between the diseased condition and the signs by which it is manifested, while in the effort at condensation much has been sacrificed in clearness.

Anatomical Atlas of Obstetric Diagnosis and Treatment. By OSCAR SCHAEFFER, M.D. With 145 Illustrations. New York: William Wood & Co. 1896.

This volume is one of a series published by Wood, of medical hand-atlases. It contains about 65 plates with 145 illustrations. The plates are the full size of the book, four and a half by seven and a half inches, and the descriptive matter for each plate is to be found on the page facing it. The plates are colored; some of them, as the anatomical dissections, elaborately

colored. They were made under the writer's direction by Mr. C. Krapf, the draughtsman to the Munich University. Many of them are excellent; but one misses, particularly in the plates of abnormal pelves, the fine photographic reproductions to be found in so many recent obstetrical works.

The latter half of the book, some 176 pages, consists of text in brief, often tabular form, giving the symptomatology and therapy of normal and abnormal labor. Under the heading "Drugs Employed in Obstetric Practice," one is surprised to find a table of 63 drugs and preparations, with doses and indications.

For use as a text-book the work is necessarily incomplete, this incompleteness being aggravated by the absence of an alphabetical index.

A Handbook on Leprosy. By S. P. IMPEY, M.D. M.C., late Chief and Medical Superintendent Robben Island Leper and Lunatic Asylums, Cape Colony, South Africa. Philadelphia: P. Blakiston, Son & Co. 1896.

This handbook has been prepared by one who has had abundant opportunity for familiarizing himself with leprosy, as it is met with in South Africa. The book pretends to be simply a practical aid to those who have had no previous acquaintance with the disease, and to these it will prove helpful. The writer's view is in general a sound one, as the theory of heredity is regarded as essentially disproved, and the active agency of the bacillus lepræ, and the consequent contagiousness of the malady are treated as settled facts. The accentuation of a form of syphilitic leprosy, and the possibility of a cure during the early stages by means of erysipelas are certainly views that offer a target for adverse criticism as the author has expected, and the weight of scientific authority will not be found on his side. We were much interested in examining the thirty-six photographs of lepers in various stages of the disease that are appended, and believe that a very fair idea of leprosy may be obtained from their study.

Syphilis in the Middle Ages and in Modern Times. By DR. F. BURET. Translated from the French, with notes by A. H. OHMANN-DUMESNIL, M.D. Philadelphia: F. A. Davis Company. 1895.

This volume constitutes No. 15 in the Physicians' and Students' Ready-Reference Series. It is a compilation of various facts concerning the existence and transmission of syphilis during the period mentioned, presented in many places in a somewhat theatrical manner. It is not improbable that evidence of value to the antiquary or the historian of syphilis may be contained in these pages, but it is difficult to understand why a collection of anecdotes and facts chiefly resurrected from the remote past of venereology, should be regarded as a useful or suitable subject for the "ready reference of physicians and students."

The Treatment of Phthisis. By ARTHUR RANSOME, M.D., M.A. (Cantab), F.R.S. London: Smith, Elder & Co. 1896.

Although devoted in the main to the treatment of phthisis, the introductory chapters of the book on the etiology, contagiousness and prevention of the disease, deserve attention as embodying Dr. Ransome's views on subjects which have been discussed not always with temperance, and on which his wide experience gives him a right to speak authoritatively. He con-

cludes with Hirsch that contagious transmission of phthisis plays but a subordinate part in the spread of the malady, nor has he yet found any satisfactory proof of infection, direct or indirect, in any well-ventilated house in this country; and this in spite of close contact, as in the attendance of a wife upon her husband, or in the nursing, and sleeping together of near relatives and friends. Moreover, experiments with tuberculous sputum show that when it can be exposed to sufficient light and air to deprive it of virulence before it can be dried up and powdered into dust no danger of infection need be dreaded. It is only where there is sufficient organic material in the air, derived from impure ground air or from the reek of human bodies, that the tubercle bacillus can retain its existence and its virulent power. Long lived though it be under these conditions it is rapidly disinfected by the natural agency of fresh air and sunlight, so rapidly, that when these agents are present even in comparatively moderate degree, the tuberculous material cannot reach its dangerous state of dust before it is deprived of virulence.

The subject of treatment is very thoroughly taken up; but the author has wisely confined himself chiefly to measures of which he has had personal experience. His recommendations are therefore made with conviction, and have thus additional force which should do much to fulfil his hope that the contents of the book "will increase the courage of the physician in the face of this terrible malady and will also provide him with arms with which he may successfully combat it."

Diseases of the Eye. A Hand-Book of Ophthalmic Practice for Students and Practitioners. By G. E. DE SCHWEINITZ, A.M., M.D. Philadelphia: W. B. Saunders. 1896.

In 1892 Dr. De Schweinitz's hand-book of ophthalmic practice for students and practitioners who desired to begin the study of ophthalmology was so favorably received that a supplementary edition was necessary two years later. Now, in 1896, the book again appears, after having been subjected to a thorough revision, and the interpolation of special paragraphs which for various reasons have not formerly appeared.

Instead of the bibliography there has been substituted a complete description of the method of determining corneal astigmatism by means of the instrument of Javal and Schiötz; unfortunately, however, the cut of the instrument which has been introduced to illustrate the method is of the model of 1889, with its unwieldy disk; and as there is another model of more recent date now obtainable, this introduction of the ancient form might be somewhat misleading.

A cut of Dr. G. F. Stevens's tropometer has also been introduced, together with an explanation of its use. The purpose of this instrument is to determine the absolute rotation of the eye, for he believes that excessive tension upon vertically acting muscles may often induce convergence and divergence independently of anomalous action of lateral muscles, and thus hopes to be able to explain certain cases of heterophoria.

The chapter entitled "General Optical Principles" has been carefully revised by Dr. Edward Jackson, and although it contains much that is elementary in its nature, it can be occasionally re-read, with profit. A chapter on "Normal and Abnormal Refraction"

has likewise received attention from Dr. Jackson, and is valuable even to the student of general medicine.

The specialist will find that the time spent on that part of the section which refers to the production and the increase of myopia and to the application of lenses for the correction of errors of refraction has not been wasted. The mention of Retinoscopy, brief as it is, will be found to be an able exposition of this objective method of determining refractive errors.

The chapter on "Operation" comprises nearly one hundred pages, and therein are described the usual methods of procedure. The successive steps are given with great clearness, and the illustrations leave little to be wished for in point of excellence.

The remainder of the volume, which is especially taken up with the discussion of diseased conditions of the eyeball and the surrounding parts, contains about everything one would expect or even wish for in a book of this sort. The classification of the various diseases is rational; the clinical descriptions are characterized by brevity and clearness, and the many sensible suggestions regarding treatment will prove a convenience when in doubt. It is noticed, however, that the classical separation into croupous conjunctivitis and the diphtheritic variety has been retained, that is, the easily to be removed membrane being characteristic of the former, and the infiltration characteristic of the latter, although cases have been lately noticed in which the membrane was easily removed and indicated the croupous variety while really containing many Klebs-Löffler bacilli. Although the different methods of treating these conditions have been gone into with great care, the most recent by antitoxin is merely mentioned.

The subject-matter, although compact, is not unpleasantly so; the illustrations are many and of a high degree of merit; and there seems to be no reason for supposing that this hand-book of ophthalmology will lose its well-deserved appreciation. W. D. IT.

The Student's Medical Dictionary. Including all the Words and Phrases generally used in Medicine, with their Proper Pronunciation and Definitions, based on Recent Medical Literature. By GEO. M. GOULD, A.M., M.D., author of "An Illustrated Dictionary of Medicine, Biology and Allied Sciences," etc., formerly editor of the *Medical News*. President (1893, 1894) American Academy of Medicine. With elaborate tables of the Bacilli, Micrococci, Leucomains, Ptomains, etc., of the Arteries, Ganglia, Muscles and Nerves; of Weights and Measures, Analyses of the Waters of the Mineral Springs of the United States, etc. Tenth edition, revised and enlarged. Philadelphia: P. Blakiston, Son & Co. 1896.

This new edition of the "Student's Medical Dictionary," the previous editions of which have met with so favorable a reception, has been rewritten so as to make an entirely new volume. The aim of the revision has been to make the book more perfectly represent the recent rapid progress in medical science. It is especially adapted to the wants of medical students, and correct and brief definitions are given of all the terms likely to be found in medical text-books. The pronunciation of the terms has been carefully and plainly expressed.

The book is of convenient size, and admirably adapted to the purpose for which it is intended.

THE BOSTON Medical and Surgical Journal.

THURSDAY, JANUARY 21, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE PLAGUE.

SINCE the epidemic of plague in the Canary Islands in 1852 this disease has been a stranger to Europe and the Western Hemisphere, if we except the insignificant outbreak in Southeastern Russia on the right bank of the Volga in 1878. It is only at long intervals that we hear anything of this pest; and in the minds of most people plague is associated with the so-called Black Death of the Middle Ages, with a destruction of twenty-five per cent. of the European population, with the names of Boccaccio and of De Foe. And yet plague has undoubtedly been endemic, and not infrequently epidemic, for a long period of time in Southeastern China, in Mesopotamia, in parts of Persia and in parts of Asia Minor. That Europe has been so free from it, and that civilized mankind has ceased to think of it as a dreadful or possible pestilence, is a tribute to the improvement in modern living.

Still, twenty-five years ago plague forced itself upon the notice of epidemiologists and public health officials by a series of active epidemic outbursts in Persian Kurdistan, in Mesopotamia on the lower Euphrates, in Arabia, in Southwestern Persia, on the borders of the Caspian Sea, and finally in Southeastern Russia, as has been said, where it was stayed. In the second outbreak in the Euphrates Valley in 1876, 20,000 persons are estimated to have perished, and in Bagdad alone it found more than 5,000 victims.

Since 1878 plague once more retired into the obscurity of its Asiatic haunts, until the sudden outbreak in Canton and Hong Kong in 1894. The mortality among the natives was very great, but scarcely any Europeans were attacked except some British soldiers who were set to cleaning out the filthy native huts. The only European civilian who contracted plague at this time, is said to have been (strange irony of fate!) the individual whose function it was to prepare the disinfectants for public use. This outbreak, however, was made memorable by the discovery and differentiation of the characteristic micro-organism of the disease. This

important addition to our still imperfect knowledge of plague was made June 14, 1894, by Kitasato, the Japanese bacteriologist, who was trained in Koch's laboratory and was a collaborator with Behring in the evolution of diphtheria antitoxin. A second epidemic of plague developed in Hong Kong in 1896, when Europeans fared less well than during the previous one.

And now Europe is compelled to give its quick thought and attention to this filth disease of woful history, by its pestilential development in the great commercial city of Bombay, and in other towns on the northwestern coast of India, which are in direct communication by the Suez Canal with European ports. There is reason to think that plague in some form has been present in Bombay since July or August, 1896. With the spread of famine in this part of India the present condition of things at Bombay is evidently most deplorable. Hundreds are dying every day, the city is being depopulated by death and flight, and the infection is spread through the surrounding country. The terrible experiences of Europe in the Middle Ages are being re-enacted, under somewhat similar conditions, in our own time.

The population of the famine-stricken portion of India is stated at 90,000,000. The average annual income of the Indian laborer has been put at eight rupees, about seven shillings English, whilst the average Briton is estimated to spend ten pounds annually upon food alone. What must be the fate of such a people when attacked simultaneously by famine and plague; by famine which creates misery and apathy, and by plague which lives and thrives upon these creatures of famine!

The labor agitator, the socialist and anarchist may well pause and reflect how far and how fast the race has travelled under reviled conditions in the Western Hemisphere!

With a vigilant application of modern sanitary methods and quarantine regulations the danger to Western countries is probably very slight. The Marine-Hospital Bureau at Washington has already put in force the former cholera restrictions, as against plague-infected ports. The government authorities of France, Italy and Austria are on the alert; and Italy has called an international conference at Rome to consider the situation.

It is to be sincerely hoped that from the present epidemic may at least come some increase of positive knowledge in regard to plague. How closely does it resemble anthrax, and how closely typhus; is the poison propagated in the soil, is it miasmatic; is it spread by animals, and by which animals besides the rat; is it contained in the excretions as well as in the blood and tissues; is it infectious by the skin, by the lungs, by the alimentary canal; what is the period of incubation; is there a pestis minor or benign plague, with a longer incubation, which may develop into the malignant disease of the great epidemics? To these and other questions, we may hope for, we may even demand, positive answers.

THE TREATMENT OF PUERPERAL CONVULSIONS.

THE subject of puerperal eclampsia has always interested physicians, and has been a favorite topic of discussion at medical meetings. Puerperal convulsions are fortunately infrequent, but when they do occur, they make a deep and lasting impression on the medical attendant, who rightly regards this as the most serious complication of labor.

The elderly practitioner, whose note-book contains the record of some fatal cases, gladly receives suggestions from his junior and inexperienced *confrère* as to how he might have saved all his patients, and at his next case of eclampsia, assisted by said junior as consultant, he is perhaps again destined to realize the uncertainty of therapeutics in this formidable malady.

One fact should be borne in mind — all kinds of treatment have succeeded and all have failed, and there is no method that can be called American, or English, or Dutch, or French. It was an error when at the recent Congress of Gynecology and Obstetrics at Geneva, Charpentier spoke of veratrum viride as the medicament of choice of American physicians. It is, on the contrary, true that very few American physicians place much reliance on this drug for the cure of eclampsia. There are many factors in the disease and many indications to meet, and the question must ever be in any particular case, What is the predominant indication?

In most cases this indication must be to arrest or to modify the violence of the convulsions. The physician had not had the care of the case before, and the convulsions have come on during labor, have become general, and threaten the very existence of the patient. Naturally he thinks of his anesthetic — of his hypodermic syringe. Most physicians at the present day resort at once to full anesthesia by ether or chloroform (the latter is more used abroad, as being more prompt in its action). There are, however, many, who, like Dr. Byers, of Belfast, at the above-mentioned Congress, rely on hypodermic injections of morphine to control the nervous hyper-excitability. It is evident that if subcutaneous injections of morphine are used in these cases where the cerebral congestion and coma are often so marked, the utmost circumspection must be employed, for the contrast is plain between the fugaciousness of the chloroform anesthesia and the long duration and intensity of that produced by morphine. There is an accumulating weight of testimony in favor of pushing the anesthetic till full relaxation is obtained, and of again resorting to it when any threatenings of convulsions appear. While the patient is under the anesthetic, there will often be an opportunity to apply forceps and terminate the labor. This will of itself have an effect in opposing the continuance of the convulsions. Where the os is not dilated, attempts may be made to produce full dilatation during the chloroform anesthesia (by digital manipulation, Barnes' dilators, etc.): these will often be effectual. Some late authors (and notably Mangiagalli,

of Milan¹⁾ regard the evacuation of the uterus as so urgent a point that they would not wait for dilatation of the cervix when the parts are contracted and rigid, but they would prepare the way for speedy delivery by multiple incisions on the os and cervix. These incisions were first proposed by Dührssen.

There is still an important indication to be met in puerperal eclampsia, that of diminishing the toxicity of the blood, the first cause of the eclampsia. This indication is a hard one to fulfil, and requires time; the most that can be done is to resort to purgations. Tarnier prescribes one drop of croton oil in a table-spoonful of castor oil, some have proposed jaborandi; and warm baths, the baths of course being impossible of administration when the patient is in convulsions. It was partly to meet this indication that bleeding was formerly resorted to, and there is, in fact, even now much authority in favor of free bleeding in eclampsia, it being supposed that several ends are thereby accomplished besides reducing the toxicity of the blood, namely, an unloading of the engorged veins of the cerebro-spinal system, and a lowering of the reflex excitomotivity.

There is only one point more to which we shall allude in connection with the treatment; these patients are generally albuminuric, and an early resort to a milk diet will materially diminish their chances of becoming eclamptic.

An able article on "The Pathology of Eclampsia" has appeared in the *Lancet* for January 7, 1897, by Dr. John W. Byers, who took part at the Geneva convention above mentioned. He says that eclampsia is a disease full of surprises, cases the most benign in appearance frequently turning out badly; while, on the other hand, the reverse is often true. After summing up the various causes which have been advanced, he decides that the toxemic or blood-poisoning theory is the only one that can now be scientifically defended. The convulsions are due to a poison arising from ordinary tissue metamorphosis, elaborated in part by the mother and in part by the fetus. Providing that this poison does not accumulate in too great an amount, and that the eliminating organs are working properly, it is got rid of without any bad effects. If, however, any of these organs (liver, kidneys, intestines) get overworked, then the poison is not eliminated, and its increased accumulation affects the nervous centres, causing the eclampsia. Leyden describes a condition of the kidney as peculiar to pregnancy: the kidney is large and pale; the cortex is yellowish and dull; there is a loading of fat about the convoluted tubes. The change in the kidneys and liver may be in the form of a parenchymatous degeneration, produced, it may be, by the poison in its circulation through them. It is in this way that the presence of albuminuria is of such importance clinically. The presence of a source of irritation in the uterus is also an element of great importance. Winckel has shown that when the fetus dies during pregnancy, the danger for the

mother is entirely overcome or much diminished. Others, as Pasquali, have called attention to this point. It must not be forgotten that the fetus in its development forms excrementitious products which must be eliminated by the mother in addition to what she has to get rid of as the result of metabolism in her own system. Chambrilont, of Bordeaux, showed in a series of experimental researches that the toxicity of the blood is increased in the fetus as well as in the mother when the latter has presented symptoms of eclamptic intoxication.

This toxemic theory, Dr. Byers thinks, is of the utmost practical value, because when the physician acts upon it as a good working hypothesis, it assists him in the prophylaxis of eclampsia. It teaches him the enormous importance of the eliminating organs in pregnancy, and when these show any sign of not acting properly, he at once puts the patient on a diet, such as milk, which gives her the least to do, and which French observers think has the power of getting rid of a quantity of the toxin; and also by hot baths and purgation he encourages these organs to act more freely.

MEDICAL NOTES.

PLAGUE REPORTED AT HAMBURG.—It is reported that the steamer *Pirrie* has arrived in Hamburg from Bombay having had seven cases of illness and one death, the mate, during the voyage. Plague is suspected. The steamer has been quarantined.

FRENCH PRECAUTIONS AGAINST PLAGUE.—The French Committee of Public Hygiene has given special instructions to the medical officers of health in Marseilles and other ports to exercise the utmost vigilance with regard to ships coming directly or indirectly from Bombay. They are directed to carry out minute individual inspection of all the sailors and of all passengers, especially of all natives of India.

QUARANTINE REGULATIONS AGAINST PLAGUE.—Surgeon General Wyman of the U. S. Marine-Hospital Service has issued an order reimposing at all foreign ports and places infected or suspected of being infected with plague the quarantine regulations which were enforced in regard to cholera in 1894. Passengers and crews who have been exposed to infection are to be detained for a period of not less than fifteen days from the last possible exposure.

THE PLAGUE IN BOMBAY.—There is no abatement in the ravages of the plague in this disease- and famine-stricken city. The death-rate is very high, and serious damage is done to the large British commercial interests in this, the principal commercial port in India. A rise of freights to Bombay was the first effect of the quarantine. The mill operatives and their families are leaving the city, thus adding a quarter of a million of famine-stricken and unemployed poor to the country districts. It is estimated that 500,000 people have fled from the city as a result of the epi-

¹ Reports of the Second Congress of Gynecology and Obstetrics, held at Geneva, September 5, 1896.

demic, and that the population is reduced more than one-half. Surgeon-Major Mauser, senior physician to the native hospital, died of plague on January 6th. According to the *Times* of India, the weekly death-rate is 200 per 1,000. Many victims refuse medical treatment, regarding the plague as a visitation from God. The plague is also raging at Kurrachee, an important seaport in the northern part of the west coast of India. Owing to false returns the mortality is probably under, rather than over-estimated.

WHERE HISTORY REPEATS ITSELF.—The announcement at the meeting of the Standing Committee of the Corporation of Bombay on September 23d by Dr. Viegas, that bubonic plague had broken out on the Port Trust Estate, and that the disease had prevailed in the locality for a fortnight to such an extent that about a hundred men had died, was naturally received with concern by the public in Bombay and of India generally. The view that Dr. Viegas was mistaken in his opinion was eagerly adopted, and a controversy ensued. Unhappily, however, subsequent events showed that Dr. Viegas' statement, as regards the presence of the plague, was only too true, and now there is a consensus of opinion that the disease prevailing in Bombay is true bubonic plague. It is remarkable that no disease has raised so much controversy as to its existence when it first appears in a locality. In every outbreak history repeats itself, and fortunately for Dr. Viegas, he lives in an enlightened age, or else he might have met with the fate of the physician, who, in the early state of the terrible pestilence at Naples in 1556—where later 6,000 died in a day, and only 50,000 survived out of 290,000—pronounced it to be the plague and was imprisoned for his audacity by the Viceroy.—*Indian Medical Gazette.*

VON BERGMANN'S SIXTIETH BIRTHDAY.—The sixtieth birthday of this eminent surgeon and teacher has recently been celebrated in Berlin. Von Bergmann is a Russian subject, as he was born at Riga, but of German parents. It is reported that when at the German Surgical Congress a Russian claimed him as a countryman, he repudiated the claim with warmth and decision. Sixteen years ago he was appointed to succeed Laugenbeck, as the first Professor of Surgery at the University of Berlin and Director of the first Surgical Clinic. We learn from the daily papers that Von Bergmann has just been summoned to St. Petersburg to operate upon the Czar, and remove a "bony excrescence in the region of the cranium," perhaps an exostosis.

CHOLERA IN ENGLAND.—The transport ship *Nubia* arrived at Plymouth, England, on January 9th, with several cases of cholera on board, among the British troops as well as the Lascar sailors. Three of the soldiers and two sailors died at sea, and another death occurred the day after the arrival of the vessel. The ship was disinfected, and the sick were removed to the hospital ship. On the following day two more of the soldiers were stricken.

AGAINST ANTIVIVISECTION LEGISLATION.—We have received a copy of a memorial (Fifty-fourth Congress, Second Session, Document No. 31) presented to the Senate by Mr. Cockrell from a joint committee of the medical and other scientific societies and educational institutions of the District of Columbia, protesting against the proposed legislation embodied in Senate Bill 1552, entitled "A Bill for the Further Prevention of Cruelty to Animals in the District of Columbia," and presenting their views on the same.

THE ASSOCIATION OF MILITARY SURGEONS OF THE STATE OF OHIO.—In response to a call of the Surgeon-General of the State, the medical officers of the Ohio National Guard met in the retiring-room of the House of Representatives, in the State House, Thursday afternoon, December 17, 1896. A constitution and suitable by-laws were adopted, forming the "Association of Military Surgeons of the State of Ohio," with active members consisting of the medical officers of the Ohio National Guard, associate members consisting of ex-medical officers of the Ohio National Guard and ex-medical officers of the United States Volunteer Service, and honorary members. The following officers were elected: President, Brigadier-General J. E. Lowes, Surgeon-General of Ohio, Dayton; Vice-President, Major L. T. Guerin, Surgeon Fourteenth Infantry, Columbus; Secretary, Major H. M. W. Moore, Surgeon First Light Artillery, Columbus; Treasurer, Major Frank Bain, Surgeon Second Infantry, Kenton. Lieutenant-Colonel William E. Waters and Captain James E. Pilcher, of the Army, were elected honorary members.

A FOOT-BALL PLAYER DIES OF TETANUS.—On November 23d, says the *Lancet* of December 5th, a member of the Royal Arsenal Foot-Ball Team at Kettering, England, sustained a compound fracture of the left radius and ulna. First aid was rendered by bystanders, and the wound was subsequently syringed and dressed with iodoform by a local surgeon. On the following day the wound was carefully syringed and dressed by the surgeon to the club. Four days later symptoms of tetanus developed, the wound was cleaned and scrubbed out, and the surgeon injected "all the tetanus antitoxin that he could get." No improvement followed, and the next day a surgeon who was called in consultation amputated the arm at the elbow. "More antitoxin was obtained and injected and the patient was kept absolutely still, as even swallowing a mouthful of water brought on a convulsion." Death took place on the 28th after a slight convulsion. It seems that the attending surgeon was able to obtain on the day the symptoms developed, only sixty centimetres of antitoxin serum, which was given in divided doses in twenty-four hours.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, January 20, 1897, there

were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 118, scarlet fever 54, measles 108, typhoid fever 23.

THE BOSTON SOCIETY FOR THE ADVANCEMENT OF PHYSICAL EDUCATION.—At the annual meeting of the Boston Society for the Advancement of Physical Education held January 13th, Dr. Clarence J. Blake was re-elected for the ensuing year. Dr. George W. Fitz proposed systematic anthropological measurement of the children in the Boston public schools—with a view of recording changes and peculiarities in growth. Dr. Hartwell, superintendent of physical instruction in the public schools, said he was heartily in favor of the idea. The members of the society concurred with the proposition made by the committee on statistics.

OUR STREETS AND OUR HEALTH.—The condition of the streets, especially of the macadamized streets, in certain parts of Boston this winter has been most trying to the health and happiness of those forced to frequent them. The inhalation of vast quantities of dust is bad enough, but dust mixed with pulverized dung is still worse. We recognize the difficulties inherent in the climate and the season of the year. But there will be no satisfactory relief from this state of things or reasonable mitigation of it, until the care of the streets is under one head and is conducted as a business enterprise divorced from politics. When will that be?

DEATHS FROM ILLUMINATING GAS.—Seven deaths from accidental inhalation of illuminating gas were recently reported in one day in Boston, and from December 1st to January 19th there were twenty deaths, more than the total number of deaths during the year beginning December 1, 1894, which was seventeen. In the year beginning December 1, 1895, there were twenty-nine deaths. A large number of deaths from the same cause is also reported from New York City.

BEQUESTS TO HOSPITALS.—By the will of the late Mrs. Ann Vose, a trust fund of \$387,966 was left upon the death of her daughter Mrs. Ann Dickinson, to be divided among local public charities, chiefly hospitals. The recent death of Mrs. Dickinson has made this fund available, and the trustees of the will are to give the Boston City Hospital, the Massachusetts Homeopathic Hospital and the Children's Hospital a considerable sum upon the condition that they each erect with the money a permanent building to be designated by the name of Vose or Ann White Vose. The amount which is to be given to each of these hospitals is to be limited by the trustees in their judgment, having regard to the whole amount of the money at their command, the other objects of the will, and the estimated cost of the buildings. The Boston Lying-in Hospital is to be given \$15,000. The surplus remaining the trustees are to apply to these institutions in the parts set against their names: Massachu-

setts General Hospital, 30 parts; McLean Asylum for the Insane, 30; Home for Aged Women, 30; Home for Aged Men, 30; Children's Mission to the Children of the Destitute, 20; managers of Boston Port and Seaman's Aid Society, 10; Massachusetts Institute of Technology, 25; Boston Asylum and Farm School, 15; Industrial Aid Society for Prevention of Pauperism, 10; Benevolent Fraternity of Churches, 10; Boston Female Asylum, 15; New England Hospital for Women and Children, 25; Perkins Institution and Massachusetts School for the Blind, 10; Boston Provident Association, 10; Boston Children's Friend Society, 20; Museum of Fine Arts, 25; Boston Young Men's Christian Union, 10; Massachusetts Charitable Eye and Ear Infirmary, 15; Massachusetts Society for the Prevention of Cruelty to Animals, 10, and the Home for Aged Colored Women, 5; Gwynne Temporary Home for Children, 10; Barnard Memorial, 10.

NEW YORK.

SEMI-CENTENNIAL OF NEW YORK ACADEMY OF MEDICINE.—The New York Academy of Medicine will celebrate its semi-centennial on Friday evening, January 29th, with exercises at Carnegie Hall.

MR. MORGAN'S GIFT TO THE LYING-IN HOSPITAL.—It is announced that Mr. J. Pierpont Morgan, the banker, has offered the sum of one million dollars to the Society of the Lying-in Hospital of the City of New York for the construction of a new building to take the place of the one now occupied by it, which was formerly the residence of the Hon. Hamilton Fish, at the corner of Second Avenue and 17th Street. The gift is made conditional on the fulfilment by the Society of two conditions—first, that it shall provide sufficient money to support the new hospital in a liberal manner, and, second, that the plans for the building shall meet the approval of Dr. James W. Markoe. Provisional plans have already been submitted by the architect of the Academy of Medicine Building for a ten-story building of granite and brick; with a frontage of 184 feet on Second Avenue and a depth of 83 feet, and it is proposed that the new hospital shall be the finest of its kind in the world. It is said that Mr. Morgan first intimated to the Board of Governors of the Lying-in Hospital about two years ago that he had such a gift in contemplation, and since then he has defrayed the travelling expenses of five of the physicians connected with the institution, who were requested to make a thorough examination of the best lying-in hospitals in this country and in Europe. One of these physicians, who went abroad for the purpose mentioned, is Dr. Markoe, and it is explained that the second condition referred to was imposed for the reason that it is owing to him that Mr. Morgan became interested in the work of the Society.

POLICEMEN ON BROOKLYN BRIDGE.—The recent resignation of one of the police force of the Brooklyn Bridge on account of the state of his health, has

called attention to the dangers attending police duty in that exposed position. The figures of this department show that 43 out of 104 policemen have died of pulmonary or rheumatic disease during the thirteen years that it has existed, and that, while there have been four dismissals for incompetence or neglect of duty, only 22 men of the original number now remain on the bridge force.

DEATH OF DR. T. T. JANEWAY. — Dr. Thomas T. Janeway, of New York, a relative of Dr. Edward G. Janeway, died suddenly on January 15th in Bermuda, whither he had recently gone to recuperate from the effects of over-work. He was a son of Col. John H. Janeway, a well-known army surgeon who was honorably retired in 1893, and was born in Princeton, N. J., in 1860. He was educated at the Philips Academy, Andover, Mass., and coming to New York to study medicine, entered the office of Dr. Willard Parker. He was graduated from the College of Physicians and Surgeons in 1885, and then became assistant to Dr. Daniel M. Stimpson, the son-in-law and associate of Dr. Parker. He remained in partnership with the latter until last autumn, when he moved to an uptown location.

Miscellaneous.

THE SEGREGATION AND SUPERVISION OF THE TUBERCULOUS.

A VERY important supplementary report on the subject of pulmonary tuberculosis, prepared by Drs. H. M. Biggs and T. Mitchell Prudden, pathologists to the Health Department, who have previously done much good work in this field, has just been made public by the Board of Health.¹ The report is too long to give in full, but the following extracts will serve to show its general purport:

Some idea of the enormous sanitary importance of the subject is obtained by reference to the records of the department showing the reported cases and deaths during the past year. . . . It may be safely assumed that from failure to properly dispose of the sputum of consumptives from thirty to fifty inhabitants of this city daily become infected by tuberculosis, and of these about one-half later die from the disease. All this suffering and death, in view of modern scientific knowledge, we know to be largely preventable by the efficient enforcement of simple, well understood, and easily applied methods of cleanliness, disinfection and isolation. . . .

We fully believe that with proper regulation tuberculosis may be restricted within the narrowest bounds, and eventually, perhaps, almost exterminated. This is not the idle dream of sanitary enthusiasts or theorists, but is a conviction founded upon the most thorough and conclusive experimental investigations, which have been amply confirmed by practical experience. In order to make possible such restriction in the prevalence of this disease, it is necessary that the Health Department shall assume a more complete and com-

prehensive control. This requires, first, the adoption of such measures as shall make possible the general sanitary supervision of pulmonary tuberculosis under well-defined conditions and regulations, differing in many respects from those applied to other more readily communicable diseases; second, the possession of such facilities for the care of the poor suffering from it as shall make possible the removal, when necessary, of those who are dangerous sources of infection.

From the beginning of this work the officials of this department have encountered, in the utter lack of proper facilities for the care of consumptives, an obstacle to practical success so great and so disheartening that we feel impelled to urge our conviction that the grave responsibilities which rest upon the Health Department in this matter cannot longer be adequately sustained without the immediate establishment, under its direct control, of a hospital for the care and treatment of this disease. . . . The best medical opinion forbids that persons suffering from pulmonary tuberculosis be treated in association with other classes of cases in the general medical wards of general hospitals. The special hospitals for the treatment of pulmonary tuberculosis now existing in this city are not free public hospitals, and are quite unable to meet the demands upon them by the poor. . . . The Department of Public Charities is not able to provide separate accommodation, excepting to the most limited extent, even for advanced cases, and as a result actual isolation does not exist in any of the municipal institutions. In every one of the institutions of the Department of Charities and the Department of Correction consumptives are found occupying beds in the general wards of the various hospitals, associating with healthy prisoners in the cells and in the greatly overcrowded workrooms of the workhouse and the penal institutions. Many of these cases, as we know from careful investigation, are sources of actual danger to their associates. . . .

There is no disease with which we have to deal in which our knowledge justifies more completely the conviction that it is absolutely preventable and that it can be stamped out by the efficient enforcement of the simple measures referred to. These measures, furthermore, involve no hardship to the individual, and when we recall that even with a reduced death-rate nearly six thousand persons died during the year 1896 in this city from tuberculosis, the vital importance of the subject is evident. We would, therefore, respectfully recommend:

First, That such action be taken by the Health Board as seems necessary and proper to at once secure the provision of hospital accommodations, under its charge, for the care of the poor suffering from pulmonary tuberculosis, who, as active sources of danger to the community may properly come under its supervision.

Second, That an amendment be made to the Sanitary Code declaring that tuberculosis is officially considered a communicable disease and formulating regulations under which its sanitary surveillance shall be exercised.

Third, That all institutions in this city which admit and treat cases of pulmonary tuberculosis be subjected to regular and systematic inspection by officials of this Board, and that specific regulations be established for the conduct of such institutions, to accord with the proposed amendment to the Sanitary Code.

¹ This report recalls a previous report from the same source in November, 1893, and the discussion at a special meeting of the College of Physicians of Philadelphia in January, 1894.

Fourth. That the scope of the measures designed for the education of the people in regard to the nature of pulmonary tuberculosis, and the methods to be taken for its prevention, be enlarged, and a closer sanitary supervision be maintained over individuals suffering from this disease in the densely populated tenement districts and in the crowded workshops and public buildings of this city.

MEMORIAL TO MICHIGAN MEMBERS OF CONGRESS, RELATIVE TO A PERMANENT CENSUS SERVICE OF THE UNITED STATES.

At the regular meeting of the Michigan State Board of Health, at Lansing, January 8, 1897, the following preamble and resolutions were unanimously adopted:

OFFICE OF THE SECRETARY OF THE STATE BOARD OF HEALTH, LANSING, January 11, 1897.

Whereas, The bill "to provide for a permanent census service" reported to Congress by Hon. Carroll D. Wright, will be of great usefulness to the sanitary service of this State, as follows: (1) by providing a more frequent statement of population, thereby affording a basis for reliable vital rates and the more accurate calculation of intercensal populations, upon which such rates depend; (2) by providing means for ascertaining, for the first time in the history of the census, a reliable representative death-rate for the State which will be comparable with those of other States and countries, Michigan being now a so-called non-registration State; (3) if Michigan shall become a registration State by act of the present Legislature for the immediate registration of deaths, by providing an annual comparative compilation of its data in connection with those of other registration States, thereby greatly increasing the usefulness of the Michigan Statistics, therefore be it

Resolved, That the Michigan State Board of Health, at its quarterly meeting held at Lansing, January 8, 1897, urgently recommends the passage of the bill for a permanent census service, on the ground of the improvement that will result therefrom to the sanitary interests of the country; and further

Resolved, That a copy of this resolution be sent to each Senator and Representative from Michigan in Congress, with the request that they labor for the passage of the measure.

HENRY B. BAKER, *Secretary*.

Correspondence.

EDWARD P. ELLIOT, M.D.

BUTLER HOSPITAL, PROVIDENCE, R. I.,
January 12, 1897.

MR. EDITOR:—The announcement, this morning, of the death of Dr. Edward P. Elliot, the first assistant physician at the Danvers Lunatic Hospital, comes as a great shock to all who knew him, and with especial force on his colleagues in the field of mental medicine. Endowed by nature with a brilliant intellect and educated in the most thorough manner for his profession, Dr. Elliot easily took rank with the ablest men engaged in psychiatric work. His personal qualities endeared him to his associates, and his modesty was such that the real extent of his abilities was fully known only to those who knew him best.

Others will elsewhere pay a fitting tribute to his memory, but I cannot refrain from the expression of my deep personal grief at the loss of a valued friend and associate and a still deeper sense of sorrow at the greater loss to the medical profession which the too early death of Dr. Elliot occasions.

Sincerely yours,

W. A. GORTON, M.D.

METEOROLOGICAL RECORD

For the week ending January 9th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 3,064; under five years of age 898; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 317, acute lung diseases 558, consumption 366, diphtheria and croup 140, typhoid fever 54, diarrheal diseases 44, scarlet fever 23, measles 16, whooping-cough 16, erysipelas 13, cerebro-spinal meningitis 7, malarial fever 4.

From scarlet fever New York 11, Boston 4, Melrose 3, Chicago 2, Philadelphia, Cincinnati and Clinton 1 each. From measles New York 8, Boston, Fall River and Melrose 2 each, Chicago and Quincy 1 each. From whooping-cough Philadelphia 9, New York and Pittsburg 2 each, Chicago, St. Louis and Boston 1 each. From erysipelas Baltimore 3, New York, Chicago, Cleveland and Pittsburg 2 each, St. Louis and Lowell 1 each.

In the thirty-three greater towns of England and Wales, with an estimated population of 10,846,971, for the week ending January 2d, the death-rate was 22.3. Deaths reported, 1,634: acute diseases of the respiratory organs (London) 348, whooping-cough 106, measles 97, diphtheria 93, scarlet fever 53, diarrhea 47, fever 40.

The death-rates ranged from 16.6 in Bradford to 31.8 in Plymouth: Birmingham 24.7, Bolton 20.8, Bristol 17.2, Croydon 16.8, Huddersfield 21.3, Hull 22.7, Leeds 25.3, Leicester 19.7, Liverpool 25.7, London 20.8, Manchester 24.9, Newcastle-on-Tyne 19.4, Nottingham 28.6, Sheffield 20.4.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 2, 1897, TO JANUARY 8, 1897.

Leave of absence for one month is granted MAJOR JAS. C. MERRILL, surgeon, U. S. Army.

CAPTAIN ROBERT B. BENHAM, assistant surgeon, U. S. Army, retired from active service by reason of disability.

CAPTAIN EUGENE L. SWIFT, assistant surgeon, U. S. Army, has been granted further extension of sick leave absence of two months.

Leave of absence for two months, to take effect on or about January 18, 1897, is granted by the Secretary of War to MAJOR PHILIP F. HARVEY, surgeon, U. S. Army.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JANUARY 16, 1897.

J. C. WISE, medical inspector, relieved from duty at the Museum of Hygiene.

J. R. TRYON, medical inspector, ordered to examination for promotion, January 11th.

G. P. BRADLEY, surgeon, ordered to examination for promotion, January 18th.

A. C. H. RUSSELL, surgeon, ordered to the "Lancaster," per steamer of January 27th.

C. T. HIBBERT, surgeon, detached from Norfolk Navy Yard, February 1st, and ordered to the "Independence."

F. W. OLCOTT, passed assistant surgeon, detached from the "Independence" on reporting of relief and ordered to the Puget Sound Naval Station.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

The next lectures will be given on Thursday evenings, January 28th and February 4th, at 8 P. M., by PROF. J. J. PUTNAM. Subject: "The Newer Views of the Nature, Causes and Treatment of Epilepsy." The profession are invited.

SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The Section for Obstetrics and Diseases of Women will meet at 19 Boylston Place, Wednesday, January 27, 1897, at 8 P. M.

Papers: D. P. Ronayne, M.D., "A Report of a Case of Suppurating Ovarian Cysts; Operation and Treatment."

E. L. Twombly, M.D.: "Vaginal Myomectomy."
F. W. JOHNSON, M.D., *Chairman*.
C. H. HARE, M.D., *Secretary*.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, January 25th, at 8 o'clock.

Dr. Clarence J. Blake will read a paper on: "Intratympanic Disease as a Factor in the Causation of Auditory Vertigo." The following gentlemen have been asked to take part in the discussion: Drs. J. J. Putnam, J. O. Green, Walton, Crockett, F. L. Jack.

Dr. W. M. Conant will read on: "Gall-Bladder Surgery." Discussion by Drs. M. H. Richardson and J. W. Elliot.

JAMES G. MUMFORD, M.D., *Secretary*, 197 Beacon St.

APPOINTMENTS.

DRS. ARTHUR L. CHUTE, WM. P. COWES and SIDNEY A. LORD, have been appointed district physicians to the Boston Dispensary.

RECENT DEATH.

JOHN JAMES SAVAGE, M.D., M.M.S.S., died in Lowell, January 12, 1897, aged twenty-four years.

With explanatory wood-cuts and text by Ernest Besnier, A. Fournier, Teneson, Hallopeau, Du Castel, Physicians to the Saint Louis Hospital, with the co-operation of Henri Foulard and L. Jacquet. Edited and annotated by J. J. Pringle, M.B., F.R.C.P., Assistant Physician to, and Physician to the Department for Diseases of the Skin at the Middlesex Hospital, London. Part V and VI. London: The Rebman Publishing Co. Philadelphia: W. B. Saunders. 1896.

Original Articles.

NOTES ON DERMATITIS VENENATA.¹

BY JAMES C. WHITE, M.D., BOSTON,
Professor of Dermatology in Harvard University.

I DESIRE to present to the Association some brief notes on the occurrence of forms of dermatitis venenata produced by certain substances which were not included in my work on this subject published in 1887, because not previously met with by me. Some of these instances have been already published,² and will only be referred to by title; the others are new to my own experience, and of them I find no reference in medical literature.

Inflammation of the skin induced by external agencies is of frequent occurrence, as illustrated by the following figures taken from the reports of my clinic at the Massachusetts General Hospital during the last seven years. In this period 20,000 new patients affected with skin diseases have presented themselves, among which were 360 cases of undoubted dermatitis venenata. Of those occurring within the past two years the exciting causes were recorded as follows: rhus, 30; iodoform, 5; articles of clothing, 5; washes of unknown nature, 7; mosquito poison, 5; kerosene, 4; furniture polish, 3; tincture of iodine, 3; chromic acid, 2; caustic potash, 2; carbolic acid, 2; caustic lime, vapor of acid, balm of Gilead, mustard water, pyocottannin, croton oil, tincture of arnica, arsenic, tincture of guaiacum with vinegar, of each one. In 35 the particular cause was not ascertained.

An analysis of the etiology of the cases extending over the seven years would have without doubt added many other irritating agents to this list, but this will suffice to illustrate the great diversity of their nature. The large proportion of unascertained causes recorded is interesting, and may be explained in various ways:

(1) The lack of observation in patients. You all know how well-nigh impossible it is to get from a great majority of persons of all classes satisfactory information as to the minutiae of their doings of a few days back only. When, therefore, in your investigation of the cause in a case of dermatitis venenata it becomes important to learn just where the patient has been, what he has done, and with what substances he has come in contact during the week preceding the beginning of the attack, one gets little assistance ordinarily from his replies. It is so customary for the patient to positively deny having been in this or that suspected situation, warranted by the appearances of the case, and later to return and say, "Oh, I forgot that I had done so and so," that I am accustomed to inform my class that, as a rule, they need not expect to learn the nature of the exciting agency in any case until the second visit. When it comes to being conscious of and later to remembering the chance breaking of a twig by the roadside, the sitting for a moment on a stone wall, perhaps, and the hundred habitual incidents of daily life, any one of which may possibly be connected with such dangers, it is not strange that the data for a satisfactory diagnosis are not generally supplied by the patient.

(2) Then we must consider how great is the number of substances ordinarily employed in the arts, with the irritating properties of which the workman is wholly unacquainted, so that he is not at all upon his guard against them. Managers do not always, I regret to say, instruct their employees as to the necessary precautions in such cases. Nor does the physician make himself sufficiently acquainted with the processes and materials employed in the arts and trades, to recognize the nature of many such cases which come to him for relief, and to warn the patient against renewed dangers.

(3) Nor must we forget the constant discovery of new chemical compounds and their introduction into manufactures of many kinds, substances of which we do not even know the name, far less their composition or properties. For such novel causes of dermatitis venenata we must always maintain an expectant attitude. And new physical forces are constantly being employed in the daily work of life, with the possible dangerous effects upon those engaged in the manipulation of which we should make ourselves familiar. As an instance, we have all, no doubt, seen a considerable variety of cutaneous changes exhibited by those who are engaged in the various applications of electricity in the useful arts, not only the result of the agencies employed in its generation, but of the direct action of the mysterious power itself.³

It is not surprising, therefore, that we so often fail to discover the immediate causes of artificial dermatitis.

Moreover, in considering the question of this or that plant or other substance as the exciting cause of an evidently artificial dermatitis, with which the patient has been in contact, we must always bear in mind the idiosyncratic vagaries of the human skin. Just as the individual stomach will not tolerate articles of food which are eaten with impunity by all mankind, so there are individual integuments which are thrown into local excitement by contact with substances which are handled by all other persons without harm. Even plants which "poison" the great majority of persons who touch them, like the venomous species of rhus, fail to produce the slightest irritation upon thorough application to the skin of a favored few. It is impossible to explain such individual susceptibility and exemption. We have to be satisfied with a word—idiosyncrasy. But we must always be prepared to recognize the working of such a law, and be justified accordingly in suspecting the commonest plant or other substance in any individual case we have to investigate.

And now let me call your attention to a brief description of some cases of dermatitis venenata hitherto commonly unrecognized.

PARSNIP—PASTINACA SATIVA.

A woman came to my office with hands and wrists greatly swollen, and the dorsal surfaces of the former thickly occupied by a papular-vesicular efflorescence in process of development. There was much heat and itching. Two days previously she had washed five bushels of recently dug parsnips and wiped them with a cloth. On the following day the inflammation began. The affected skin was of a peculiar lurid color. No other explanation of the dermatitis was apparent. As she lived at a considerable distance from Boston no subsequent observation of the case was possible.

³ See Journal of December 3, 1896, for an account of severe dermatitis produced by exposure to Röntgen rays.

¹ Read at Meeting of American Dermatological Association, September 8, 1896.

² On *Primula obconica*, Garden and Forest, February 29, 1889; Boston Medical and Surgical Journal, May 1, 1890. On Poisoning by "Violet Water," Boston Medical and Surgical Journal, December 12, 1889.

Speaking of this case to my class, one of the students informed me that he had seen men and boys present a vesicular dermatitis of the hands and wrists after weeding parsnips. As many as three or four of a gang would be affected.

Very few of the umbelliferous plants contain principles capable of exciting cutaneous irritation. In my book on dermatitis venenata I mention but three: *ferula gabaniflua*, the source of galbanum; *thapsia garganica*; and *heracleum lanatum*. The latter (cow-parsnip) is closely allied to edible parsnip in its botanical features, and its leaves when applied to the skin may produce vesication. Our garden parsnip (*pastinaca*) runs wild, it is well known; and its root is described as then degenerating in esculent properties and becoming poisonous. It may be that both foliage and root retain under cultivation properties which are irritating to some skins.

HAMAMELIS VIRGINIANA.

Can hamamelis produce inflammation of the skin?

I was consulted by a man at the hospital, who had applied to his shoulder, on account of rheumatism, a mixture of laudanum and hamamelis. The whole upper chest, upper arm, and neck were occupied by large vesicles, oozing areas, and confluent papules. No other applications had been made. Of course, there is no certainty as to the composition of preparations labelled hamamelis, and it is not impossible that some of the principles of laudanum may be irritating to the skin of some persons, although I have never known it to act in this way.

Witch-hazel is used to such an enormous extent as a household external remedy that cases of cutaneous irritation should be familiar to us all, if it were possible of exciting it except in the rarest instances. One manufactory in Boston is said to use a ton and a half of leaves and three and a half tons of bark a year in the preparation of the "extract." It must be placed in the suspected class.

OLEUM CASSIÆ.

I would record here an instance of inflammation of the skin excited by oil of cassia, which was presented by our associate, Dr. Greenough, at a meeting of the Boston Dermatological Club. I take the liberty of mentioning it in his absence.

The patient was a girl engaged in dipping wooden toothpicks in oil of cassia for the purpose of giving them an agreeable odor. A few days after entering upon this occupation her hands began to show signs of irritation, and she was obliged to leave it after a fortnight, at which time she was exhibited to the society by Dr. Greenough. The hands then smelt strongly of cinnamon. Their dorsal and lateral surfaces and the front forearms were greatly inflamed, and occupied by vesicles and oozing areas. The face was red and blotchy, and the lower abdomen was reported to be affected in a similar way, no doubt by prolonged contact with the hands during sleep.

Cinnamic aldehyde, the essential principle of cassia bark and flower buds, produces no irritating action upon the integument, so far as I have hitherto known. The possible presence of adulterants in substances which are only rarely the cause of dermatitis should be borne in mind as an explanation of such action. Petroleum compounds have been found in commercial specimens of the oil.

HOP HORNBEAM—OSTRYA VIRGINICA.

I beg your attention to the following note from Charles Sprague Sargent, Professor of Arboriculture and Director of the Arnold Arboretum, Harvard University. He writes: "Do you know about the stinging properties of the hairs which grow at the base of the fruit of the hop hornbeam? On my hands they cause an irritation which does not entirely disappear for several hours. I find no reference to this fact in any of the books to which I have access."

This small tree, growing in all parts of the United States, attracts notice through the resemblance of its pendulous fruit to hops, and its wood is much used on account of its hard quality. I was not aware of such irritative properties, and should be pleased to hear if members of this Association have knowledge of such. It may be another explanation of some of the many cases of dermatitis which we so often meet with and cannot refer to contact with any well known poisonous plant, although confident that they are due to some such cause.

ANILINE BLACK.

An account of several cases of dermatitis in members of the Boston Fire Department produced by wearing black shirts.

On June 22d, a fireman presented himself at my clinic with bands of dermatitis around the neck, wrists and lower nates, hips and upper thighs. The penis was also inflamed. The appearances were those of infiltrated erythema of a brilliant red color, decidedly elevated above the general surface, occurring either in uniform areas of considerable extent, or in smaller, discrete circular patches, varying in size from a pea to a dime. The latter lesions were sharply defined and somewhat resembled those of urticaria rubra, although not fugitive. There was no sign of vesiculation or excoriation upon the affected areas. The bands of inflammation around the neck and wrists were from two to three inches in width, and were abruptly defined above and below. The central lower affected region was some five or six inches in width, and was not so sharply outlined. The penis was greatly swollen and reddened, and twisted upon itself. The subjective symptoms were not as intense as might have been presupposed, a mild degree of burning and itching only. There was no associated disturbance of the general economy.

The peculiar distribution of the appearances suggested at once the artificial nature of the dermatitis, and as it was apparent that it was sharply limited to parts where the collar, cuffs and flaps of the outer shirt projected beyond the lines of the undershirt, inquiry was directed to the former garment. It was learned that some two or three weeks previously the Fire Department had issued new black cotton shirts as part of the prescribed summer uniform. They were worn over an undershirt, and had a rolling collar, projecting cuffs, and were considerably longer than the latter. It was learned also that another fireman in the same house was similarly affected.

The symptoms had not developed for ten days or thereabouts after the shirts were first worn, and this proved true in the other cases subsequently treated. During this earlier period the weather had been exceptionally cold for the season, and it was not until this was followed by a period of excessive heat that the inflammation of the skin developed. Then it was

that the portions of the shirt in direct contact with the parts above indicated became moistened by perspiration and actively irritating.

The attention of the Fire Department was called to the case, and inquiry was instituted with regard to the possible existence of other instances. During the following few days three other firemen appeared at the clinic in a similar condition. The appearances were wonderfully identical in all of them: uniform areas of perfectly smooth, elevated infiltration of varying extent, with sharply defined abrupt borders, occupying portions of the trunk, especially where the underclothing was pressed in closest contact with the integument. In one of the later patients the parts affected were the same as in the first instance, but in the others large areas upon the trunk were intensely inflamed, and it was learned that the wearers were profuse sweaters and that their undershirts were saturated with perspiration in consequence of their ardent occupation. In no instance did the inflammation extend below the lower level of the garment on hips, buttocks and thighs. In three of the patients the penis was affected.

Two shirts were issued to each man, and each was worn for a week without washing. It was during the wearing of the second shirt, that is, during the intensely hot weather of the second week, that the cases developed. In a subsequent instance a shirt which had been washed retained undoubtedly its irritative properties. In two of the cases the affected areas on the arms passed later, in consequence of continued friction and scratching, into a true eczematous condition.

During the period of observation of the affection among the firemen an out-door laborer came to the clinic presenting similar cutaneous manifestations, which had appeared a few days after wearing a black shirt made apparently of the same material. In this case, too, the dermatitis was sharply limited to the regions covered by the garment.

June 26th, a shirt belonging to one of the firemen most seriously affected, one which had been worn a few days before the outbreak and which had been thoroughly moistened by the underlying shirt, and which had not been washed, was sent to Prof. William B. Hills of Harvard University for analysis. His report follows:

BOSTON, July 13, 1896

DEAR DOCTOR:—I have completed my analysis of the black shirt which you left with me a fortnight since, and have not been able, using about a square foot of the material, to detect any metal other than iron; antimony, arsenic and chromium are absent. The compound of iron commonly used in the manufacture of aniline black is the chloride, and this is supposed to exist in the fabric in some sort of combination with the pigment.

It would seem that the irritant action of this material is due either to the iron compound, or, more likely, probably to the coloring-matter itself, or to some other organic material entering into the composition of the coloring matter, or employed in fixing the color upon the fabric.

I suspect that some of these cases of eczema are due to the pigments themselves; but, so far as I know, the action of these is unknown. I do not think their action has been studied experimentally. It has been customary to attribute the effects to arsenic, antimony, etc., especially in cases in which the compounds of these metals are present in the fabric, and to let the matter rest there. In this case something else is evidently the offending material.

I do not know of any facts warranting an opinion that iron has the same irritant action that arsenic, antimony and chromium have in the combinations used in printing

and dyeing; and, it seems to me, we must look upon the pigment itself, or upon some other organic constituent of the fabric, as the *probable* cause of the trouble.

Yours truly,

WILLIAM B. HILLS.

THE TREATMENT OF DISABLED JOINTS RESULTING FROM THE SO-CALLED RHEUMATOID DISEASES.¹

BY JOEL E. GOLDTHWAIT, M.D., BOSTON.

DURING the past few years it has been my fortune to see a large number of patients with reference to the treatment of stiff or deformed joints which have resulted from the so-called rheumatoid diseases; and from a careful study of the cases certain points have been suggested in regard to the diagnosis and the treatment which seem to me to be of enough importance to be brought before this Society for discussion.

My apology for presenting a subject in which there is so little general interest is that the impression made upon me by seeing so many of these helpless cripples has been most profound; and it is my chief desire and hope that by the discussion of the subject here a more definite understanding of the disease may be obtained, and that it may be possible to hold out more encouragement to those afflicted with diseases than which none that are non-mortal can be worse.

The cases, as they have been seen, have varied greatly, both as to the extent of the disease and the degree of deformity. In some of the mildest only one or two joints have required treatment, while in the worst cases almost every joint in the body has been affected, the condition being not unlike that seen in the pitiable subjects who are exhibited as ossified men and women in our cheap museums. Most of the cases have been seen at the Carney or the Good Samaritan Hospitals; and I am indebted to the members of the staff of both hospitals for referring the cases to me, and for their aid in carrying on the treatment.

All cases have been excluded in which the joint disability resulted from acute inflammatory rheumatism, and also all cases in which the trouble developed in connection with gonorrhea, typhoid fever, or the other infectious diseases. In these cases the treatment is more definite and the prognosis more or less certain. Only those cases have been considered in which the diagnosis of rheumatoid arthritis, or some of its synonyms, had been made by the physician in charge, and in which the diagnosis was borne out by the pathological changes which it was possible to study clinically. Among all the cases which were grouped under this head, there were two distinct types, which presented entirely different features, and which were affected so differently by treatment that a brief description of their distinctive features is necessary before any report of the treatment can be given. Please understand that the classification is purely a clinical one, and is not based, as should be the case, upon a careful bacteriological and pathological study. Such work is being carried on, but as yet the observations are too few from which to make any deductions. It is for this reason that I have not attempted to suggest new names, but have used those which have long been employed, giving them perhaps a somewhat different meaning.

¹ Read at the Surgical Section of the Suffolk District Medical Society, November 4, 1896.

One of the two types I have called "rheumatoid arthritis," and the other "osteo arthritis." Both terms are incorrect; but they may, perhaps, serve until more advanced work has determined the cause of the disease and the exact nature of the morbid anatomy.

The cases designated by the term "rheumatoid arthritis" are less frequent than those of "osteo arthritis," but develop more rapidly and lead to much more permanent crippling. Rheumatoid arthritis seems to be essentially a disease of atrophy, and is characterized by a spindle-shaped swelling of the joints during the acute and the subacute stages, which afterwards subsides leaving the joint smaller than normal. In the fingers the line of the joint is smaller than the rest of the finger, instead of larger as is normal, due to the atrophy of the ends of the bones and the articular structures. The skin over the joint is also much atrophied, the normal wrinkles being obliterated. The deformities are due, except when the disease has come on very early in life before the bones have ossified, to muscular atrophy or the continued unvaried position of the affected part. They are usually deformities of flexion or extension, there rarely being any lateral distortion, such as is common in joints affected by the other type of the disease.

The patients have been chiefly women, and the disease has developed at two distinct periods of life, at adolescence and from middle life to old age. In the former the disease runs a more acute course, more of the joints are involved at one time, and nearly all of the affected joints become firmly ankylosed as the inflammatory process subsides. The disease of middle life or old age is much less acute than in adolescence, developing more slowly, with rarely more than two or three joints inflamed at a time. With these cases it has taken from four to five or six years for the disease to develop, while with the younger patients, one, two or three years have shown the disease well advanced. Firm ankylosis is much less frequent in the disease occurring after middle life. The joints may be partially ankylosed and the function much impaired, but the destructive process is less marked than with the younger patients.

Fig. I shows the appearance of the fingers, with the spindle-shaped enlargement about the joints, as is seen during the acute or subacute stage of the disease. This swelling is due almost entirely to change in the soft parts and peri-articular structures, the bone being but little if any involved, as is shown in the radiograph, Fig. II. It is seen in this that there is considerable swelling about the joint, but the appearance of the bone is normal, except that the line of the joint is somewhat indistinct, due to the change in the cartilage.

Figs. III and IV illustrate the same condition after the acute symptoms, with the swelling, have subsided. The atrophy of the joint is plainly shown, the joint line being the smallest part of the finger. In both patients the finger joints were ankylosed. Fig. III represents the hand of an old person, while Fig. IV is the hand of a young woman. The contrast between this condition and that represented by Fig. V is certainly very evident.

Osteo arthritis is much more common than rheumatoid arthritis, but rarely leads to permanent crippling, and is characterized by a proliferation of the cartilage, with the formation of osteophytes, at the ends of the bones. This is essentially a disease of middle life or old age, and the joint disability is due to the mechanical

presence of the masses of bone or cartilage. The distortion of the part is due also to the presence of this hypertrophied tissue, and as the growth is rarely equal upon the two sides of the joint there is almost always some lateral deformity. The joint is usually more or less flexed, owing to the presence of the osteophytes or cartilage on the dorsal aspect of the joint. These rarely if ever occur in the flexure of the joint, so that hyperextension is never seen as in rheumatoid arthritis. In osteo arthritis the joint is larger than normal, as is shown in Fig. V, the reverse of rheumatoid arthritis. The change in the bone is shown in Fig. VI.

The most common form of osteo arthritis is that seen so frequently in both men and women in the form of Heberden's nodes (Fig. V), at the phalangeal articulations. While this in the large majority of cases may interfere with the use of the joint to a certain degree, it does not cause serious trouble. If, however, an injury is received, the hypertrophy of the cartilage and the formation of the osteophytes goes on much more rapidly, and may very seriously disable the joint. This, it seems to me, is a point of much importance, and explains in part why seemingly simple injuries in middle-aged or old people often result in long confinement and permanent impairment of the use of the joint. In such cases a much more serious prognosis should be given.

In support of this statement, the following cases are reported in considerable detail:

CASE I. Miss E. M., sixty-five years of age, a nurse by occupation, was referred to me at the Carney Hospital by Dr. J. C. Warren. For many years the finger-joints have been enlarged, but she has been able to do her regular work and aside from this has been very well.

About two and a half years ago the patient fell into a cellar-way, receiving a small scalp wound and a severe contusion of the right knee. The left knee and right arm were considerably strained, but not as severely as the right leg. The left arm escaped entirely. Because of the injuries she was taken to the Massachusetts General Hospital, where she remained for two or three weeks, and was then transferred to the St. Luke's Convalescent Home, where she remained for six or eight weeks. After this she was as well as ever for a few months, but then began to be troubled with needle-like pains in the knee-joints, chiefly the right. These pains were quite constant, and grew worse, so that it was more and more difficult for her to be about.

A year and a half after the injury the right knee commenced to catch occasionally on walking. This grew worse, so that the patient was frequently thrown down by "the locking of the joint." Because of this and the feeling of insecurity and helplessness which it produced, the patient was referred to the Orthopedic Clinic at the Carney Hospital.

When first seen, in July of this year, the right knee was considerably swollen, partly due to synovial fluid and partly due to thickening of the ends of the bones. Several loose pieces of cartilage were easily felt. In the left knee there was somewhat the same condition, but less marked, and, while some loose bits of cartilage could be felt, they were evidently still attached to the synovial membrane. Some thickening of the bones at the right elbow could be felt, and the thickening of the humerus at the shoulder was very marked. The left arm was apparently per-

FIG. V.

FIG. II.

FIG. VI.

FIG. I.

Rheumatoid arthritis, showing the spindle-shaped enlargement of the first phalangeal articulation, as is seen during the acute and sub-acute stage of the disease.

FIG. II.

Rheumatoid arthritis, showing no change in the outline of the bones in spite of the marked spindle-shaped enlargement of the joints. The line of the first phalangeal joints in the index and middle fingers is less distinct than normal, due to the atrophy of the cartilage and the ankylosis of the joint.

FIGS. III, IV.

Rheumatoid arthritis, after the spindle-shaped swelling has subsided, showing the constriction at the joint due to the atrophy, instead of the nodular enlargements as seen in "osteo-arthritis." Fig. III is the hand of an old person. Fig. IV, a young person. All of the joints in both of these hands were still.

FIG. V.

Osteo-arthritis, showing the nodular enlargements (Heberden's nodes) at the second phalangeal articulations.

FIG. VI.

Osteo-arthritis, showing the bony deposits upon and enlargement of the second and third phalanges, causing the lateral distortion.

FOLD

OUT

fectly normal. The Heberden nodosities were present at the phalangeal articulations of both hands.

The patient was admitted to the hospital, and a few days later the right knee-joint was opened by Dr. Balch, and three loose cartilages, as large as hickory-nuts, were removed. At this time the joint was carefully explored, and the rim of new-formed cartilage could be seen as well as felt, and in some places it was quite nodular, showing plainly the origin of the loose bodies.

The subsequent history has been uneventful. There has been no more locking of the joint, although it is probably only a matter of time before some of the other pieces break off and cause trouble.

CASE II. Miss J. A., eighty years old, has always been well and strong, except for trouble with the hands, supposed to be "rheumatism."

Two and one-half years ago the patient was struck by a carriage and knocked down, producing a severe contusion of the right hip and knee, and which confined the patient to bed for a few weeks. After this she was about as well as ever until a few months later, when occasional sharp, needle-like pains were noticed, chiefly in the right knee. This grew steadily worse, the function of the joint becoming more and more impaired and walking more and more difficult. It was because of the pain and the lameness that the patient sought treatment.

Upon examination, the right knee was considerably swollen, the swelling being partly synovial, but chiefly due to the thickening of the bones. The right patella was fully twice as wide as the left, and the rim of cartilage, which had been thrown out at the edge of the articular surface of the femur, was so distinct that it could be pinched between the fingers. What was apparently a similar condition was present at the hip.

None of the other joints showed any signs of active increase of the articular structures. The Heberden nodes at the finger-joints were quite marked, and the thickening was enough to produce considerable lateral deformity.

In both of these cases the change in the joint is apparently produced by a single severe trauma, but the same condition may result from a series of comparatively slight injuries. I have seen one or two cases in women, who were dressmakers, and who were complaining of trouble in the knees, which was apparently due to trauma received by dropping on to the knee or knees in fitting dresses.

The following case is reported more fully to still further emphasize this fact:

Mrs. L. B., seventy years of age, has been well, except for "rheumatism" of the hands, until the past five or six years. Since then she has been unable to continue her occupation, that of putting down carpets, because of the trouble with the knees, kneeling being almost impossible.

Upon examination, both knee-joints were enlarged, the enlargement being due partly to synovial distention and partly to thickening of the bone and cartilage. Both patellæ were fully twice their normal width, the edges being irregular. There was a large nodular thickening about the end of the femur, apparently a rim of new-formed cartilage. There were several pieces of loose cartilage which could be easily felt. The other joints, aside from the nodes on the fingers, showed no change.

The trouble with the joints in this case was prob-

ably due to the constant bruising received in dropping on to the knees in the patient's occupation of carpet-laying.

These cases are reported thus carefully to suggest at least, if not to prove, that what seem to be simple injuries of joints, occurring in persons having a tendency to osteo arthritis, as shown by the enlargement of the phalanges, are followed in many cases by a more or less rapid increase of the cartilage of the injured joints, even though this special joint may have shown no evidence of the osteo-arthritic change before. The increase in the cartilage is at times sufficient to render the joint useless, and the liability to this condition should be borne in mind in giving a prognosis in apparently simple joint injuries.

We must turn now, to that which is properly the subject of this paper, the treatment of the joints disabled by these diseases. The general treatment, including forced diet, stimulating bathing and massage, as well as the medicinal treatment, is of much importance, but more properly belongs to the realm of general medicine, and has been quite fully described in the general text-books and the magazine articles. In these articles, as well as in the works on surgery and even the works on orthopedic surgery, the surgical or mechanical treatment of these conditions is either passed over entirely, or, if it is mentioned, it is in the most superficial way and with the most discouraging prognosis.

In the cases which I have treated, no new or brilliant methods have been employed; and if the results have been any more encouraging or satisfactory than those of other writers, it has been due partly to the classification of the cases, and partly to a most careful and persistent attention to all of the details of treatment.

It is evident at once that the two forms of the disease, or possibly the two diseases, which differ so essentially in their clinical aspects, should require different modes of treatment. In the one, a disease of atrophy characterized by firm ankylosis of the joints, more active methods can be used than in the other class, in which any trauma or forceful movement would cause a more rapid development of the hypertrophied tissue, and greater impairment of usefulness.

In neither case should a complete restoration of the normal functions of the joints be expected. Both forms represent what are considered incurable diseases, and the improvement following the treatment, is improvement in degree only. The patient may still be a cripple, but instead of being absolutely helpless she may be able to take care of herself.

For the cases designated as osteo-arthritis, all manipulation of the joint or forcible correction of the deformity should be most carefully avoided, and the joint protected and immobilized as much as is possible or practicable. The presence of the newly-formed cartilage mechanically interferes with the motion, so that in each movement of the joint, the bones strike against some portion of this new tissue. This constant irritation acts as a stimulus and causes a more rapid development of the cartilage and a still greater impairment of the joint. Forcible manipulation would not only increase this irritation, but would possibly dislodge some of the cartilage, forming a loose body, which in its turn would cause more irritation to the joint. Rest and quiet for the joint is of the first importance, not necessarily an entire disuse of the part, but use in

such a way that the joint is injured as little as possible. If complete immobilization is desirable, the plaster-of-Paris or the leather splint give the best results; but in the majority of cases some motion may be allowed, and a jointed splint, permitting certain degrees of motion, or even the flannel bandage applied over several thicknesses of cotton, will give all the needed support.

The result of free motion is not only to increase the development of the cartilage, but from the internal trauma which results, a subacute synovitis follows, and this at times from the distention of the capsule and the consequent loosening of the ligaments, causes considerable annoyance. Aspiration of the joint in this condition has been very satisfactory.

In the cases of rheumatoid arthritis the affected joints should be used as little as possible, and never manipulated until the inflammatory process has entirely subsided. If treatment be undertaken before this not only will the individual joint be made worse but the disease as it shows in the other joints will be made more acute. Up to this time the treatment should be wholly general.

After the evidences of active disease in the joint have disappeared, more definite measures should be taken to preserve or restore the motion. If, as is frequently the case, there is complete ankylosis, the patient should be etherized completely so that the muscles are entirely relaxed, and the joint flexed first and then extended through the extreme normal limits. This should be done but once and the joint put absolutely at rest. Any malposition of the bones should be corrected at this time. The free manipulation of the joint, the so-called "pump-handle" manipulation should never be attempted in these cases, it being followed by acute pain and swelling, and practically always, so far as I have observed, resulting in an even firmer ankylosis than before.

After the joint has been bent once, always with the flexion first, it is immobilized, and not disturbed for three days. The dressing is then removed, and motion attempted by the patient, no force being allowed. The dressing is then reapplied as carefully as before. At first scarcely any voluntary motion will be possible, but the attempt should be made twice each day, the joint being kept perfectly quiet between times.

This treatment should be continued for several weeks and the dressing not entirely removed until the muscular spasm has disappeared. In the first few weeks when this spasm of the muscles is so marked decided benefit results from the use of hot-air baths. The temperature of the air should be from 250° to 275° F., and the bath should be used for a half-hour each day. This not only relieves the muscular contraction but is claimed to stimulate the secretion of the joint fluid.

After the spasm has disappeared more active measures should be attempted. The patient should be given more active work and massage, and passive manipulation should be used.

In following this course of treatment very little pain results and what there is, is commonly referred to the muscles, probably the result of use after long inaction. There should be very little if any joint effusion as the result of the forcible breaking up of the ankylosis, and rarely any ecchymosis.

A movable joint should be the result in the large

majority of cases, but the degree of motion will vary according to the joint involved, the amount of displacement of the bones, and the character of the adhesions. The more complicated the joint the less satisfactory will be the result. In the knee it will depend very largely upon the patella. If this can be freed and kept free the motion will be good, but, if it becomes adherent, a considerable amount of motion may still be present as the result of the stretching of the patella tendon, but the voluntary control of the joint will be much less perfect, and a splint will probably be necessary.

In the articulations in which the tendons lie close to the joint, as at the wrist, the restoration of motion will be more difficult than where the joint is more protected.

The prognosis as regards the hip joint is very good, and in one case in particular normal motion has resulted.

In the ankles and in the joints of the fingers and toes, the results have been fairly good. The chief difficulty at the ankle, consists in gaining the dorsal flexion. The joint is invariably ankylosed with the foot extended, the position at times having existed for years. During this period the calf muscles contract, and it is this shortening which limits the flexion. To meet this condition, the traction shoe devised by Dr. Shaffer, has been of great help and is to be used after the spasm has disappeared, when the passive manipulation is desirable.

The knee-joint is almost invariably found flexed, with some dislocation backwards of the tibia, and with this subluxation there is usually an outward rotation of the leg and foot. To meet this condition, the joint is first flexed as much as possible, the patient being etherized, and then by means of the genu-clast, described in another paper,² the bones are brought forward into their normal position. It is impossible to accomplish this replacement of the bones, when the deformity has existed for any considerable time, with the hands alone.

The different cases, as they are seen, present so many different features as to the number of joints affected and the degree of disability; and the possibilities of treatment and the results of treatment vary so much in the different cases or the different joints, that it is impossible to form any statistics, or to make any more than general deductions from a series of such cases. Each case must be considered by itself, and rather than burden you with a detailed account of each patient, which would be not only wearying but of little value, I have selected two or three of the worst cases for detailed report, feeling that this will show, more clearly than any statistical table, the nature and extent of the improvement which is to be expected in these cases.

CASE 1. Miss L. G., thirty-three years of age. Thirteen years ago patient began to have trouble with "rheumatism." The disease has gradually progressed, one joint after another becoming involved, so that during the past six years the patient has been absolutely helpless, confined to her bed and dependent upon others for every detail of personal care. During the past five years there has been little or no change in her condition.

When first seen, a year and a half ago, nearly all of the joints of the body were ankylosed. There

² See Boston Medical and Surgical Journal, September 7, 1893.

was slight motion in the left shoulder and a few degrees at the left elbow; but aside from this, the joints of the arms and hands, with the exception of slight motion in one or two fingers, were entirely useless. In the left hip the motion was quite free; but aside from this, there was little if any motion in the joints of the legs and feet.

For the past year and a half, during which time the patient has been under my care, she has been etherized twice. At each time the adhesions in a number of the joints have been broken up, and this has been followed by constant gentle manipulation. Between the manipulations the joints have been protected with splints, and these continued until the patient was able to control the joint herself.

The improvement has been considerable. The patient is still much crippled; but instead of being absolutely helpless, she can take care of herself. She is able to go about the room without assistance, and with the aid of crutches can go up and down stairs. Besides this she is able to take quite considerable walks out of doors.

The condition of the special joints is of interest. The hips have nearly the normal amount of motion. The knees can be fully straightened; the right can be flexed to a right angle, while the left has about half of this motion. The motion in the feet and ankles is quite free. There is about one-half the normal amount of motion at the shoulders. In the elbows there has been no improvement, but the hands and fingers are decidedly better so that the patient has been able to make several patterns of Danish lace, by which she hopes to partially support herself.

CASE II. Mrs. D., seventy years of age. For the six years previous to 1892, the patient had been entirely confined to her bed, or to a wheel-chair because of "rheumatism," which had gradually developed. Both legs were involved, the knees being chiefly disabled, so that walking or standing erect was impossible. The hands and arms were considerably affected; but with the exception of the fingers, the joints were not ankylosed.

During the past four years the patient has been under my care at intervals. At the first the joints were manipulated without ether, and the contraction of the knees partially overcome with splints and extension. In two months she was able to walk with two canes, and soon after this the wheel-chair was discarded altogether. It was possible for her to go up and down stairs, and to go freely about her room.

Two years ago, in the depression caused by the death of a daughter, there was an exacerbation of the disease, which lasted with more or less severity for fully a year. Since then the treatment has been continued, and she is once more able to be about her rooms, using one or two canes.

These two cases represent the two extremes as regards the time of onset of the disease, the first patient being a young woman, and the second a woman quite advanced in life. In the younger patient the disease had been more acute and rapid in its development, and more joints were disabled as the result. Because of this and, as the youth of the patient made it possible, more active treatment was carried out than in the other case. Ether was given twice, and the joints freely manipulated. In the second case, because of the age and the general condition of the patient, the manipulating of the joints was entirely carried on

without an anesthetic, the progress being much slower than in the first case. Both cases are much better than before the treatment, and both have been able, after a long period of confinement to bed or a wheel-chair, to be up and to walk about, either without any support or with the aid of cane or crutch.

CASE III is another instance of the disease of the later period of life; but as it occurred in the early part of this period, it was possible to carry on a more active treatment.

Mrs. R., fifty-eight years of age, has been crippled with "rheumatism" for the past eight years, and for five years has been confined to the bed or chair, walking or standing erect being impossible.

The patient was first seen by me about eight months ago. At that time, both knees were flexed at a right angle and both joints partially ankylosed. The patellæ were firmly adherent, so that extension of the legs was impossible.

There was some motion at the ankles but the tarsal and phalangeal joints were stiff. The arms were somewhat affected, none of the joints being firmly ankylosed, but there was a restriction of the motions in nearly all.

The patient has been etherized twice. The patellæ were dislodged and the knees straightened with the knee apparatus (mentioned above), and the joints of the feet and toes were manipulated and the adhesions broken.

At the present time she is able to go about her rooms using crutches and wearing a pair of caliper splints to support the knees. There is a steady improvement, and during the next year, I feel sure that she will be able to do very much more.

In these and in the other cases the progress has been checked and the treatment stopped, at times, by the starting up of the disease in some new joint, or by an exacerbation of the disease in some joint in which the disease had been comparatively quiescent. In no case, however, has the disease reappeared in the joints which were being manipulated. Apparently when the disease disappears from the joint, and the joint structures are so disorganized that it becomes ankylosed, that joint is no longer affected by the disease. That the acute manifestation of the disease in the other joints, is partly, at least, due to the treatment is not improbable.

CONCLUSIONS.

Of the cases classed as rheumatoid arthritis two types are described, clinically, which for convenience, are designated rheumatoid arthritis and osteo arthritis. The differentiation between the two types is of the utmost importance in the treatment.

Rheumatoid arthritis is much more acute than the other; it occurs in middle and advanced life, but early in life as well. During the acute stage the joints show a spindle-shaped swelling, which finally subsides, leaving the joint much atrophied, and usually ankylosed.

For these cases the joints should be manipulated after all acute symptoms have disappeared, and the character of the manipulation is of much importance. Cases are reported showing the results of treatment in this class.

Osteo arthritis is a much more chronic condition, occurring only in middle life or old age, and is characterized by a proliferation of the articular cartilage,

with the formation of nodes about the joints. These cases should not be manipulated, as any injury or undue violence results in a more rapid development of the cartilage. It is this tendency which explains the impairment of function which so often results after comparatively simple injuries to a joint. Protection and immobilization in such cases is of importance.

NOTES ON ACTINOMYCOSIS.¹

BY HERBERT B. MCINTIRE, M.D., CAMBRIDGE, MASS.

THE disease now known as actinomycosis has long been recognized in various parts of the world as a disease not infrequently occurring in cattle. So long ago as 1833 it was carefully studied by Dr. Dick, and was locally known in England as "cycers." In Germany it seems to have more frequently attacked the tongue, and was then called "Holz zunge," while a dozen other names were given more or less descriptive of the disease. Occasional cases occur in this country, and are known among farmers as "lumpy jaw." It was not until 1876 that a scientific investigation of the disease was made. Bollinger made a careful study of many cases. He examined the fungus which had already been noticed by earlier observers, and brought the subject before the scientific world. He submitted specimens to the Botanist Harz, who described and classified the fungus and gave it its name. This disease was undoubtedly observed in man long before this time, but not until 1878 were the first observations published by J. Israel. In 1885 Dr. Harley reported the first case observed in Great Britain. He reported this as a "case of tubercular disease resembling actinomycosis." Not until after six cases were examined post-mortem in England was one recognized during life. Following this many specimens which had long been in museums and described under various names were examined and found to be genuine cases of actinomycosis.

The first two cases observed in America were reported by Dr. John B. Murphy to the Chicago Medical Society in 1885.² Both cases were of the jaw and recovered.

Actinomycosis is a chronic disease due to a local infection with the ray fungus. This may enter the body by the respiratory tract, by the gastro-intestinal canal, by the mouth or rarely through the broken skin. Once introduced the disease extends to adjacent tissues and is carried by the blood-vessels to different parts of the body, in this way starting new centres of infection.

Boström, followed by other experimenters, made cultures of the fungus. Johnie and Pontick inoculated cattle by injections into the peritoneal cavity, but Pontick failed to convey the disease to animals by feeding them on the infected tissues. Dr. D. E. Salmon in his investigations for the United States Government placed twenty sound animals in the midst of a herd having discharging sores, and compelled them to eat from the same feeding-boxes. At the end of four months not one of these animals had contracted the disease. Although two or three cases are on record which were supposed to be due to direct contagion, it now seems probable that men and animals contract the disease from the same

source, namely, the cereals. It seems likely that the fungus exists in some other form upon grain, and only develops into its now recognized form when introduced into animal tissues. In most cases it has been impossible to discover the source of infection. Soltman describes the case of a boy who swallowed an awn of barley. This was afterwards found in an abscess behind the sternum and was surrounded by nests of ray fungi.

The pathological conditions, methods of staining and microscopical appearances of the fungus have been recently treated of by Dr. F. B. Mallory in a valuable paper.³ I wish to acknowledge my indebtedness to this paper for helping me in the diagnosis of the case which I shall report to-night.

I make the following quotation from Professor Crookshank's report on actinomycosis published in the report of the Department of Agriculture to Parliament in 1888. It may be of help in making a diagnosis where the necessary staining solutions and a high power objective are not at hand. He says:

"The fungus can be detected by the naked eye in the discharge. On spreading this on a glass slip the largest tufts of the fungus were found to be about the size of the head of a small pin. They had a distinctly sulphur-yellow color by reflected light, but appeared yellowish or greenish-brown by transmitted light. Examined with an inch objective they had the appearance of more or less spheroidal masses of a pale, greenish-yellow color. After pressing down the cover-glass the grains flatten out like specks of tallow. On again examining with the same power they were found to have fallen apart into a number of irregular and sometimes wedge-shaped fragments of a faintly brown color, affording a characteristic appearance. By preparing another specimen and covering it with a cover-glass without completely flattening out the grains, the spherical, oblong and reniform masses of which the tufts were composed were recognized with a one-sixth inch objective as the familiar rosettes of clubs which are observed in cattle."

The prognosis in cases affecting the mouth and skin is generally favorable. Over half of the cases reported have recovered. In lung and intestinal cases little is to be expected without the future throws some new light on the disease. Two lung cases have recovered by opening spontaneously through the chest walls. The treatment is as yet largely experimental. Thomassen claimed that by charging the blood with iodine the further development of the fungi may be prevented and the disease cured. This he did by the administration of large doses of iodide of potash. Professors Oestertag and Meunier support this treatment.

Dr. Salmon, Chief of the Bureau of Animal Industry, has tested the iodine treatment extensively in cattle. He stated in his report that "the effect of the medicine by far exceeded the expectations. With a few exceptions, they all showed wonderful improvement. Under the effect of a twelve- to fifteen-gram daily dose, those large fetid ulcerating granulomas would dry up and shrink, most of them disappearing altogether."

Meunier treated a case occurring in the cervical region of a man with 25 grains a day of potash iodide, and the patient was quickly cured. Locally the treatment is becoming more conservative. Formerly extensive excisions of the indurated tissues were made,

¹ Read before the Cambridge Medical Improvement Society.

² New York Medical Journal, vol. xli, p. 17.

³ Boston Medical and Surgical Journal of March 28, 1895.

which now seem unnecessary. "Schlange emphasizes the relatively great tendency of actinomycosis to a spontaneous cure when the fungus may readily reach the outer skin, and there be thrown off as a foreign body or sequestrum, as in the neck and on the cheek. In those fairly numerous cases, it was sufficient to make a simple incision and scrape the softened points. Where the process extends into the deeper tissue layers, it may be necessary to render possible the spontaneous extrusion of the fungus by laying bare to a large extent the diseased region." The fungi are destroyed by exposure to oxygen. Various disinfectants are also useful, such as carbolic acid, tincture of iodine, peroxide of hydrogen, methyl-violet, etc.

I was called to see Mr. W. on March 2, 1895. He gave me the following history: Age fifty-one years, a veteran of the Civil War, native of Cambridge, of healthy American parentage. Nearly his whole life since the war had been passed in Cambridge and in Boston, and the last five or six years he had been in a hat store. During this time he had been abroad twice to buy goods, visiting France and Germany. The last trip was made two years before. He had had no severe illness, but for several years had been somewhat of a dyspeptic. For some months he had been "running down," and for the past three or four weeks he had suffered from pain starting in the gastric region and extending to the left. This and a swelling which he had noticed to the left of the stomach caused him to call a physician. He had also lost strength and failed in general health and appetite. The patient was in bed. His face showed signs of pain. His color was good, and he looked well nourished. The respiratory movements of the left side were much restricted. The respiratory murmur was indistinct over the lower half of the left lung. No dulness on percussion or change in voice sounds could be made out. In front was a swelling, the lower and inner border of which was well defined by the cartilage of the eighth, ninth and tenth ribs of the left side. It extended up to the nipple. The surface was not reddened. The swelling was evidently outside the ribs, and had a peculiar feeling of firmness as though it were bound down very firmly. There was marked pitting on pressure. The stomach was much distended with gas, so that the whole area of the swelling was tympanitic. Bowels constipated. No cough. Respirations 24, pulse 72, temperature 99.2°. During the next few days patient remained about the same. The condition of the stomach improved under a careful diet and *nux vomica*. Radiating pains continued in the left side. The temperature was slightly elevated.

On March 14th Dr. Hildreth saw the case with me. The pain was more localized near the centre of the swelling, which had become reddened. Here the inflammation had gone on to breaking down of the tissues, and there was a boggy place the size of a half dollar. The respiratory movements of the left side were even more restricted, and slight dulness could be detected over the lower lobe.

On the 18th Dr. Hildreth again saw the case with me. Ether was administered. An incision was made over and parallel to the seventh rib. At a depth of one-half inch a cavity was found. This was about two inches in length and one in width. It was filled with a grayish, granular, cheesy mass—probably less than one ounce in quantity. The incision was enlarged to the full length of the cavity. This was carefully

scraped out with the finger and a curette, and examined for any sinus. This was the more carefully done, as we had expected to find caries of the rib. However, nothing was found; and after washing the cavity with corrosive-sublimate solution, it was packed with iodoform gauze. The induration and hardening of the tissues was well shown in the subsequent dressings, for on removing the packing the lips of the external wound did not tend to close. For two weeks following the operation the patient's condition remained about the same. The pain was relieved, but the temperature rose to 100° at night, with a pulse of 90. The respirations were 25 when in bed.

Early in April a few drops of pus were found on the dressings, and in this were seen some peculiar yellowish granules. At first I thought this due to the iodoform gauze, but with plain sterilized gauze the same granules were seen. My suspicions were aroused; and on April 5th I prescribed iodide of potash in eight-grain doses, three times a day, and watched the discharge. This was so slight that no satisfactory specimens could be obtained, but I believed that I found the ray fungus. On April 19th I handed a small specimen to Dr. Cogswell, and asked him to search for actinomycetes. His report rendered the diagnosis certain. The iodide was now increased to 45 grains daily, and this was continued in increasing doses up to 90 grains a day. The wound was washed out with corrosive-sublimate solution, permanganate of potash or peroxide of hydrogen.

By May 1st the patient seemed to be rather improving. He was up a part of the day. He walked slowly and drawn over to the left side. The respiration, always rapid, became much more so on exertion. The area of dulness over the back of the left lung had increased. The respiratory murmur was heard very faintly. The voice sounds were heard more distinctly than over the sound lung. There was slight cough. On May 25th measurement of the chest during moderate inspiration showed the left side to be one inch the smaller (15½ inches). I now found a slight swelling over the twelfth rib of the left side, about four inches from the spine. This gradually increased, and by June 10th had become red and boggy. Strong objection was made to any farther operation although the pain had become severe. With a hypodermic syringe I injected into this boggy mass 15 minims of a five-percent. solution of permanganate of potash. This was followed by marked relief from pain.

On June 12th the patient began to cough, and after several hours began to raise large quantities of thick, tenacious, white expectoration. This came in such quantities as to cause intense feelings of suffocation. Probably eight or ten ounces were raised during the night. Following this both cough and expectoration almost ceased. I could find no nests of actinomycetes in the expectoration, nor were they found later on microscopical examination by Dr. Cogswell.

By June 21st the swelling in the back had again become very painful. Near its centre had appeared a fluctuating tumor the size of a horse-chestnut. This was very red and dotted with 30 to 40 white points looking like a carbuncle. On lancing, this discharged about an ounce of pus which contained the characteristic fungi.

During the remainder of June and July he was fairly comfortable. The front wound still discharged a little, and both openings had a tendency to bleed. Slight

fever continued, but he was able to get up a part of the day. He laid on the piazza, and took up his old habit of smoking. Appetite fairly good. The sore on the back was gradually changing its position, by healing of the first openings and the forming of new ones farther from the spine.

During August, while I was away on my vacation, Dr. S. E. Wyman took care of the case, and no particular change was noticed. As I looked back over the case I could see that the patient had lost strength and flesh.

During September the yellow granules entirely disappeared from the front opening, and this healed. The discharge from the back had increased but contained fewer nests of actinomyces, and was thinner. During the most of the time since early in April he had continued to take the iodide, and had borne it well. For the past two or three months a little morphia was required to procure rest.

On October 6th he was taken with severe pain in the right side of the chest, and friction sounds were found. His condition became such that no thorough examination could be made. The necessary dressings were changed with great difficulty, and he gradually sank, dying on the 18th of October.

No autopsy was allowed. This is much to be regretted, as the disease is yet so rare. I have carefully examined the vital statistics of Massachusetts so far as they are accessible, and cannot find a case of death reported from this cause.

In this case I believe the infection took place through the bronchial tubes. I am satisfied that the iodide of potash had no control over the progress of the disease.

THE STERILIZATION OF CATGUT BY BOILING ALCOHOL.

BY RALPH C. LARRABEE, A.B., BOSTON.

THE peculiar word *catgut* is said to be derived from an obsolete term *kitgut* or *kitstring*, the word *kit* meaning a fiddle. Catgut is made from the intestines of sheep. These are first passed between rollers to remove their contents, then macerated in a solution of potassium hydrate, scraped and again rolled.¹ This removes everything but the submucous layer and of this layer alone catgut consists. The intestinal tube retains its integrity, so that, till the final steps of twisting and drying, it can be inflated throughout. Sometimes the whole tube is used, sometimes it is split and only the half away from the mesentery is employed. Each finished strand consists of several tubes twisted and dried together, the number depending on the size. Most of our catgut is probably imported, but there are a few factories in the United States.

Especially where the intact tube is used, the bacteria originally inside the gut are still enclosed in a firm animal membrane. To a much greater degree than those found in silk they are protected from the action of antiseptics. Maceration and putrefaction play an important part in the preparation of catgut. There is every opportunity for the presence of all the bacteria of putrefaction as well as for those which, normally or abnormally, may be found in the intestines of living sheep.

¹ A. W. Booth: *Therapeutic Gazette*, x, 810, 1894.

The flora of catgut consists mainly of non-pathogenic organisms. According to Koch the pus-producing bacteria are seldom found. The germ almost invariably present is the hay bacillus (*B. subtilis*), non-pathogenic. In a large series of cultures made by Lauenstein,² bacillus subtilis was almost always found, while occasionally was found the micrococcus tetragonus, staphylococcus albus, and "a large coccus." The potato bacillus (*B. mesentericus vulgatus*) non-pathogenic, is also frequently present. It is said that the tetanus bacillus occurs in the intestines of herbivora.³ It is not improbable that some specimens contain anthrax spores, as our catgut comes largely from abroad. If an animal once had anthrax, the spores would be quite certain to appear in catgut made from its intestines. In point of fact, however, actual cultures generally show only non-pathogenic forms. Nevertheless, several epidemics of wound infection, rightly or wrongly attributed to improperly sterilized catgut, have occurred in Germany and one at least in this country. The resistant character of many of the bacteria found is great. Though cultures rarely if ever show tetanus or anthrax, one must always bear in mind the possibility of their presence and adjust his methods of sterilization accordingly.

Chemically, catgut contains water (23 per cent.) and fat (7.5 per cent). In many methods of sterilization these substances must be removed. A large part of the remaining bulk consists of collagen, which, under the action of hot water and presumably in the wound, becomes gelatin.

The great advantage of catgut, and an advantage possessed in like degree by no other suture material, is its ready absorbability. Its great disadvantage is its difficulty of sterilization; none of the usual methods can be used. This is especially unfortunate in a material designed to be absorbed in the wound.

In estimating the value of any method of sterilizing catgut two criteria are to be regarded: first and foremost, its germicidal efficacy; second only to this, its effect on the quality of the gut. The method must also be reasonably simple and reasonably cheap.

Of the many ways proposed to render catgut sterile, that of boiling in alcohol seems to have the greatest merit for simplicity of apparatus and ease of obtaining the material. Boiling in 95-per-cent. alcohol has been used in at least two hospitals in this city, and has given clinical results, on the whole, satisfactory. But at the Children's Hospital cultures of a bacillus like that of tetanus, though probably non-pathogenic, have been obtained from gut so prepared. I boiled specimens of Sizes 0 and 1 catgut in 95-per-cent. alcohol for one hour, and in each case obtained cultures of a bacillus which I could not identify with any known pathogenic organism. It will be seen that as a germicide ordinary alcohol has little power. It will probably kill the pus organisms, but not the more resistant germs whose presence there is reason to fear. Boiling in alcohol under pressure gives better results, but requires apparatus not commonly at hand.⁴

Recently Saul⁵ has published experiments showing better results obtained with simple modifications of the method. He boiled catgut, previously disinfected by heat and reinfected with anthrax, in several differ-

² Archiv. f. klin. Chirurg., 50, 323, 1895.

³ Répin: *Annales de l'Institut Pasteur*, viii, 170, 1894.

⁴ Répin: *Loc. cit.*

⁵ Untersuchungen über Catgut-Disinfection, Archiv. für klin. Chirurg., lvi, 98, 1896.

ent alcohols, namely, methyl, ethyl, propyl, isobutyl and amyl. None of them, not even amyl, boiling at 132° C., would kill the bacteria when used absolute for three hours. The addition of water increased their sterilizing power up to 20 per cent., which is the largest amount of water that can be used without injury to the gut. Boiling 80-per-cent. ethyl alcohol killed anthrax in an hour.

Saul also found that if catgut was boiled in a five-per-cent. solution of carbolic acid in absolute alcohol, three hours were not enough to kill anthrax-bacilli dried upon it. But the same amount of carbolic in 90-per-cent. alcohol would kill in less than ten minutes of boiling. He accordingly recommends the following method: The catgut, rolled or fastened on glass plates, is put in a tight receptacle with a condenser and immersed in

Absolute alcohol	850
Deliquesced carbolic acid	50
Water	100

It is then boiled gently for fifteen minutes. The method he said did not impair the strength or quality of the gut. Its great simplicity and brevity make it desirable to know more of its results.

Unfortunately, Hofmeister⁶ reports several cases where this method was used in which post-operative abscesses followed. Bacteriological tests showed the gut to contain staphylococci. These results are not a little surprising and puzzling. Many have found gut boiled in 95-per-cent. alcohol good enough for most purposes and all agree that the addition of water increases the sterilizing power. It is hard to think that the carbolic acid would decrease it. Hofmeister does not report having used any special means of bacteriological testing, probably his cultures and Saul's were made in about the same manner. Yet the gut which he used, when it reached the patient, contained organisms which Saul's did not. As both were put through the same process, it would seem that Hofmeister's gut must have been reinfected after sterilization, in storage or handling.

There is one other possibility. Saul experimented, as I have said, with gut previously disinfected and reinfected with anthrax bacilli. Possibly the alcohol-carbolic solution reached these, as they were only on the outside, but could not affect germs in the deeper layers. It seemed to me that experiments must be done with the organisms present in the catgut when it was made. It also seemed desirable to determine what difference was made by the size of the catgut and to test its strength when sterilized and preserved in various ways.

The apparatus which I used was similar in principle to that used by Dr. H. J. Hall.⁷ The gut to be tested was cut into short pieces and put with the alcohol-carbolic solution of Saul into a flask with a long glass tube for a condenser. The temperature was then raised in a water-bath till the alcohol had boiled for the desired length of time. Cultures were made by dropping the bits of gut, with sterile forceps, into bouillon and leaving them in the thermostat for a week, after which, if there was no growth, they were considered sterile. Many of the cultures were watched for over two weeks in order that the bouillon might thoroughly soften and penetrate the specimens. It may be objected that the bits of gut might carry enough

carbolic acid to inhibit growth. It was found, however, that the coarser sizes which would carry the greatest amount of carbolic, were the ones from which the growths invariably appeared when the boiling was too brief. I obtained thus several luxuriant growths from large samples of the coarsest sizes in very small amounts of bouillon. I used gut from four different sources. My results may be tabulated as follows. The figures represent the number of cultures, positive or negative.

SAUL'S SOLUTION—ALCOHOL AND CARBOLIC ACID.

Size	00	0	1	2	3	4	5	Boiled.					
								15 min.	30 min.	45 min.	1 hr.	1 1/2 hr.	2 hr.
	00	0	1	2	3	4	5	3	3	3	3	3	3
	0	0	1	2	3	4	5	3	3	3	3	3	3
	1	1	1	1	1	1	1	3	3	3	3	3	3
	2	1	1	1	1	1	1	2	1	3	2	2	2
	3	1	1	1	1	1	1	1	3	3	2	2	2
	4	1	1	1	1	1	1	1	4	1	5	5	5
	5	1	1	1	1	1	1	1	1	1	5	5	5

It will be seen that up to Size 2 fifteen minutes was enough to sterilize, and that up to Size 4 thirty minutes was sufficient. Four out of five specimens of Size 4, boiled thirty minutes, gave negative cultures. Ten cultures from the two largest sizes and several from the smaller, boiled forty-five minutes, were negative. In all, six cultures out of forty were positive, these being from the largest sizes boiled only fifteen and thirty minutes.

These results show a fact not brought out by previous experiments with this solution, that the amount of boiling needed to sterilize catgut depends very largely on the size of the gut, but that even the largest sizes can be rendered sterile if they are boiled long enough.

From the bouillon cultures I made cover-glass preparations and gelatine cultures. Some of the latter resembled anthrax, but inoculation into a guinea-pig proved that they were not. Dr. A. K. Stone kindly examined the cultures and slides and in his opinion, they "resembled those of no known pathogenic organism."

To compare approximately the power of this solution with that of alcohol I experimented briefly with Sizes 0 and 1. I found that with Size 0 fifteen minutes of boiling in Saul's solution were enough to sterilize, but an hour in 95-per-cent. alcohol was not. Size 1 was sterilized in ten minutes by boiling in Saul's solution, but not in an hour by 95-per-cent. alcohol.

I also tested the tensile strength of gut prepared by Saul's method and preserved in various ways, by finding what weight the sample, always knotted, would sustain. Three sizes were used, 0, 2 and 4, and for each size the various experiments were made with samples from the same piece. Each of the following results is the average of three tests:

- (1) Raw catgut, 15 $\frac{3}{4}$ pounds.
- (2) Gut coiled in rings, boiled fifteen minutes in Saul's solution and tested after several hours' drying, 11 $\frac{3}{4}$ pounds.
- (3) Wound on glass tubing, boiled forty-five minutes and dried for several days, 14 $\frac{1}{2}$ pounds.
- (4) Wound on glass tubing, boiled forty-five minutes and preserved in Saul's solution for several days, 14 pounds.
- (5) Wound on glass tubing, boiled forty-five minutes and preserved dry for six weeks, 12 $\frac{3}{4}$ pounds.
- (6) Wound on glass tubing, boiled forty-five minutes and preserved in Saul's solution for eight weeks,

⁶ *Beitrag. z. klin. Chirurg.* xv, 836, 1896.

⁷ *Warren: Surgical Pathology*, Appendix.

10 $\frac{1}{2}$ pounds. One of the samples used in this test broke at such a low point that it was probably due to an accidental imperfection in the gut. The strength of the other samples was about the same as for the corresponding sizes tested dry.

According to these figures, the gut keeps its strength better when wound on pieces of glass tubing than when simply coiled. This is because the coils allow the gut to shrink and untwist. In the smaller sizes coils are converted, during boiling, into mere snarls. The larger the tubing the better. Short pieces of glass tubing are better than spools, as they permit the catgut to be wound in a single layer. It is desirable to do this that the solution may come in free contact with all parts.

The method is so simple that long preservation is neither necessary nor desirable. Whether preserved dry or wet, a certain per cent. of the strength is gradually lost. That preserved dry seems to be a little stronger; but when preserved wet it is more flexible, and will probably be found easier to work with. Wet or dry, it is not at all slippery and appears to the eye unchanged.

To summarize: Saul's method is safe and convenient when used as follows:

(1) Wind the gut in a single layer on pieces of large glass tubing.

(2) Place in a tightly-stoppered flask with a condenser consisting of a glass tube at least five feet long and penetrating the cork. Boil by means of a water-bath in Saul's solution (absolute alcohol 850, carbolic acid 50, water 100) for forty-five minutes. For the largest sizes one hour is safer, and for the smallest thirty minutes are enough.

(3) Remove the condenser, insert a sterilized stopper and preserve in the same flask and solution used for boiling; or, pour off the solution, insert a sterilized cotton stopper and preserve dry.

In conclusion I wish to thank Dr. H. C. Ernst, who kindly allowed me to work in the Bacteriological Laboratory of the Harvard Medical School.

Medical Progress.

REPORT ON NEUROLOGY.

BY PHILIP COOMBS KNAPP, A.M., M.D.

TREMOR.

LAMARCO¹ opened a discussion upon tremor, at the Congress of French alienists and neurologists at Nancy, by stating that a portion of the body trembled when it described rhythmical oscillations on either side of its position in equilibrium. He classified them as tremors during rest (the type of paralysis agitans) and tremors on voluntary movements (the type of disseminated sclerosis); or again, as slow tremors (three to five per second, as in paralysis agitans and senile tremor), medium tremors (six to seven per second, as in disseminated sclerosis), and rapid, vibratory tremors (eight to nine per second, as in exophthalmic goitre and general paralysis). Tremor of the hands is found in 40 per cent. of normal persons; it does not differ from emotional tremor, and is of the neuropathic type; a similar vibratory tremor is seen in 34 per

cent. of hysterical patients, 85 per cent. of neurasthenics, 20 per cent. of epileptics, and 25 per cent. of the insane. It is therefore of great symptomatic value in neurasthenia. The finer tremors of the tongue and eye-lids often escape observation; if instruments of precision were used to detect tremor the percentages would be larger. Tremor is often associated with other abnormal movements; it may co-exist with chorea, or a mercurial or saturnine tremor may be transformed into an arrhythmical movement. In alcoholism, general paralysis or sclerosis tracings often show that the rhythm of the tremor is altered, in a transition to arrhythmical movements. There are also transition forms between the tremors during rest and those during movement; mercurial tremor exists in repose, and takes on a special form on motion; in paralysis agitans tremor may be produced only under the influence of muscular effort; senile tremor may be provoked by muscular contraction, may exist in repose, and be increased or suppressed by motion. Hereditary tremor may not differ essentially from senile tremor, and the tremor of sclerosis may be seen in meningitis or hemiplegia. A given tremor, therefore, does not always correspond to definite lesion because certain forms are ill defined. Tremor may be only an unimportant episode or a symptom of great value. We cannot yet distinguish between tremor as a functional symptom and as a symptom of a focal lesion. A vibratory tremor is common in health, and the similar tremors of emotion, neurasthenia and exophthalmic goitre may be only an exaggeration. The tremor of paralysis agitans is the only one which seems characteristic. The "epileptoid trepidation" of ankle clonus is, however, of very great value as indicating sclerosis of the lateral pyramidal tract.

Croq thought that many of the so-called normal persons manifesting tremor might be neurasthenic, alcoholic or hysterical. Paralysis agitans and hysteria might co-exist, producing two forms of tremor. Sabrazès and Cabaunes found vibratory nystagmus in hysteria, of spontaneous origin, much more rapid than in disseminated sclerosis, sometimes accompanied by internal strabismus, persisting on distant vision and checked or produced by suggestion. Parizot had found by delicate instruments that tremor is universal and physiological, the amplitude of the vibrations being the only distinguishing feature. Bernheim claimed that all forms of tremor was cured or relieved by suggestion except that of paralysis agitans. Parant regarded tremor of the tongue as a favorable sign in melancholia.

TIC DOULOUREUX.

Dana's successful method of treating the severe forms of trigeminal neuralgia by drugs and regimen without resorting to surgical interference has already been mentioned in the JOURNAL.² Ewart³ has also urged the efficacy of suitable medical treatment. The lack of unanimity in the pathological reports shows that the trouble is not due to a simple mechanical pressure, capable of relief only by surgical means, and the success of the operation of removal of the Gasserian ganglion, shows that the trouble is, as a rule, of peripheral origin, that is, that the peripheral sensory neuron is alone involved. While this operation, and

¹ Revue Neurologique, August 15, 1896.

² See JOURNAL, cxxxv, 21, July 2, 1896.

³ British Medical Journal, November 21, 1896.

perhaps this operation only, is an effectual method of relieving the pain, the risks are still so great as to render it a last resort, and consequently any method of relief by medical means is much to be desired. Ewart argues that in all cases there is a functional or constitutional factor in the production of the trouble, and in some of them this factor is paramount. In one class of cases he thinks that a gouty connection is well established, the trouble occurring in those obviously gouty, or those in whose family gout has often occurred, or those who have previously suffered from visceral affections probably of gouty origin. The presence of gouty disturbances may often be overlooked, but careful search will usually indicate it. The special indications for treatment are sedative, restorative, alterative and tonic. Sleep is essential, and sufficiently strong narcotics should be given to produce it; morphine and chloral are especially recommended. The restorative methods include mental and bodily rest and suitable nourishment. Rest in bed is indicated in all severe cases. Nourishment is essential, but it must be adapted to the tenderness of the mouth and the weak digestion. A modified vegetable diet and a diminution of the nitrogenous foods are desirable. Alcohol is, as a rule, to be avoided. If dyspepsia be present it should be relieved, if possible; but it is often helped by alterative remedies. The most efficacious alteratives are the salts of iodine, and mercury. Iodide of potassium may often be combined with the tincture of iodine, and the addition of mercury often gives relief where the iodine and its salt have failed.

The tonic measures depend less upon drugs than upon hygiene and moderate muscular exercise. By these methods of treatment Ewart has obtained brilliant success in a number of severe cases, which he reports, where other forms of treatment and even surgical operations on different branches of the nerve had failed. All his reported cases, which had been sent to the surgeon for operation, improved and lost the pain for a time. How far operation may be postponed or ultimately avoided is still a question, but if the symptoms can be checked once it is possible that they may also be checked again at any relapse. In this country the influence of gout is naturally less considered. The chief points of harmony in the methods employed by Dana and Ewart seem to be in the use of rest in bed and of mercury and iodide of potassium. These drugs alone, without the rest, are sometimes of remarkable efficacy in cases where there is no probability of syphilis. Ewart has given iodide of potassium in moderate doses, six to ten grains, at times with the addition of twenty to thirty drops of tincture of iodine. Larger doses, from half a drachm upward, are usually tolerated, and seem to be more efficacious.

ANTERIOR POLIOMYELITIS.

Medin⁴ has made a careful study of 93 cases of infantile paralysis occurring in Stockholm; of these 43 occurred in an epidemic in 1887, and 21 in an epidemic in 1895, the other 29 occurred sporadically in the intervening period. He considers the chief cause of the disease to be a specific infection, but, while the transmission from one person to another is certainly possible, he holds such transmission to be extremely rare. He found no predisposing causes,

except that it is most common before the age of four; there is no special difference in frequency between girls and boys. The epidemics occurred at the same period, late summer and early autumn, when cholera infantum is most common, but this affection was not especially common during the epidemics. In only a few cases was there a prodromal stage. Most cases began with fever, but sweating was rare; somnolence was somewhat commoner, dyspeptic conditions were very common, intestinal catarrh, constipation and also retention of urine. He noticed frequently pain and tenderness, especially in the legs. Convulsions in the initial stage were more rarely observed than is generally supposed, contractures were never seen, and deep sighing and the hydrocephalic cry were very rare. In two cases, after the fever had subsided, it recurred. In 1887, 28 of the cases were typical anterior poliomyelitis, and in 1895, 13. In some of these cases the thoracic and abdominal muscles were affected on one side. Of 50 cases the legs were affected in 45, the arms in 14, the face or the eye muscles in four. Multiple neuritis in an acute form was seen six times in the epidemic of 1887 and at least twice in 1895. It usually came on suddenly, without prodromes, and was attended with initial fever lasting a few days. Pain occurred early and cutaneous hyperesthesia, which in one case went on to total anesthesia, was occasionally observed. Acute transitory ataxia, due probably to changes in the peripheral nerves, was seen in five cases. The medulla was frequently affected; in eight cases there was facial paralysis, and one of these cases which terminated in death showed degeneration in the facial nucleus. Abducens paralysis was seen in six cases and hypoglossal paralysis in five, in two of which the autopsy showed changes in the hypoglossal nucleus. In three cases there was accessory paralysis. Two cases died with symptoms of acute dyspnea, and the autopsy showed changes in the vagus nucleus. In three cases there were symptoms pointing to disturbance in the oculo-motor nuclei. Acute polioencephalitis was observed in both epidemics, an indication that this trouble is due to the same infection as the spinal form. Medin thinks it not improbable that acute polioencephalitis in its acute stage may occur at the same time as poliomyelitis or some other local process in the nervous system, and that infantile paralysis is not always and exclusively a spinal disease. The prognosis is worse when the disease is located in the lumbar cord, and better when in the cervical cord, and it is more favorable in multiple neuritis than in poliomyelitis. The younger the child is the worse the prognosis and the more significant the results. The autopsies showed signs of general infection: in the brain there was only hyperemia, in the cord were signs of an intense inflammatory process proceeding from the vessels in the whole anterior horn, degeneration of the ganglion cells and nerve fibres, with secondary degeneration in the lateral columns, and degeneration of the bulbar nuclei. He considers the disease as independent and individual and he would separate from infantile paralysis all paralytic affections which occur in connection with other infectious diseases.

LANDRY'S PARALYSIS.

Bailey and Ewing⁵ have made an elaborate study of this affection in so thorough a fashion as to remove

⁴ Nord. med. Ark., N. F. vi. 1; Ref. in Neurol. Centralblatt, December 15, 1896.

⁵ New York Medical Journal, July 4, 11, 1896.

much of the obscurity which has so long hung about it. They report a case in a woman of thirty-six, which conforms exactly to Landry's clinical type. The woman had acute ascending paralysis, which in six days had involved all the limbs, and in ten days proved fatal; it caused death by invasion of the bulbar nuclei, without marked sensory impairment, without involvement of the bladder and rectum, and with retained faradic excitability of the muscles. The autopsy showed congestion and edema of the lungs, acute degeneration of liver and kidneys, and acute hyperplastic splenitis; the nervous system macroscopically was normal. Microscopically, however, extensive changes were found involving the whole cerebro-spinal axis, affecting chiefly the gray matter of the brain and medulla and the anterior horns of the spinal cord. The character of the lesion was that of an acute exudative inflammation, with marked cellular infiltration of the circumvascular sheaths, degeneration of the ganglion cells, and obliteration of other structural elements. After an exhaustive study of the literature they insist on adhering to Landry's original definition of the affection as an ascending paralysis which pursues a rapidly fatal course without sensory symptoms, holding that it forms a clinical entity too distinct to warrant enlarging it so as to include cases in which sensation was decidedly affected or completely lost, and in which the disease was distinctly subacute or chronic, with intervals of improvement. By including such cases the doors are thrown open to a multitude of cases of neuritis, and Landry's paralysis becomes a disease of frequent occurrence and heterogeneous character. Landry held that there were no lesions in the nervous system, which was corroborated by Hun in 1891, but the use of more delicate methods of research have modified this opinion. In 28 out of 44 cases lesions were demonstrated in the central nervous system alone, or in the central and peripheral nervous system. In 16 cases where no lesion at all was found, the nerves were not examined in six, and in none were the modern stains, notably Nissl's, used. The writers conclude that acute ascending paralysis is an acute toxemia in which the poisonous agent affects chiefly the nervous system. The commonest seat of the lesion is in the spinal cord and in the medulla, and it may be present in the cortex and in the nerve roots. When in the spinal cord the lesion is that of acute anterior poliomyelitis — namely, an acute exudative inflammation, following the distribution of the central branch of the anterior spinal artery, with cellular infiltration of the circumvascular sheaths, degeneration of ganglion cells, loss of structural elements, and with or without degeneration of the anterior roots. The lesions in other parts of the cerebro-spinal axis are of a similar nature. The evidence that the lesion of typical Landry's paralysis may exist in the peripheral nerves alone is based upon a single case reported twenty years ago by Dejerine. When the lesion affects the peripheral nerves there are increase of neuroglia cells and degeneration of nerve fibres. It is at present impossible to deny that acute ascending paralysis may run a fatal course without leaving demonstrable histological changes in the nervous system. It is certain the cases with negative pathological report did not present the marked vascular lesions of acute anterior poliomyelitis, but it seems probable that in these cases there were changes in the ganglion cells demonstrable by delicate methods. Bacteriological examinations have been undertaken in a

few cases, with the result that staphylococci, streptococci and other bacteria have been occasionally found. Absolute demonstration of the dependence of the disease upon specific bacteria, by producing similar symptoms in animals after inoculation of pure cultures, are still lacking, but the disease is undoubtedly of toxic and very probably of bacterial origin.

CEREBRAL COMPRESSION.

Neumayer⁶ has studied the histological changes in the cerebral cortex which follow pressure, a subject to which thus far little attention has been paid, except with regard to pressure upon the spinal cord. Neumayer introduced foreign bodies between the skull and the dura in rabbits, by making a very small trephine opening in the skull, taking especial care to avoid hemorrhage or any injury to the membranes, and enlarging the opening with bone forceps. Sterilized leaden bullets were then carefully introduced, and kept in position by the introduction of a soft sterilized wax. The pressure thus produced was continued for variable periods and then the animals were killed and the brain cortex examined by various methods. Three animals were killed within twenty-four hours. The cortex showed signs of degeneration in the nerve cells and fibres of the most superficial layers, the layer of tangential fibres and the layer of small pyramidal cells. Three other animals were killed after the pressure had lasted from one to ten days. The degenerative changes had in these extended deeper, but were of the same nature. A new condition was also present in the superficial layers, an increase of the supporting tissue at the expense of the nervous elements and thickening of the pia. Five animals were examined after the pressure had continued from ten to sixty days. There was a progressive decrease in the nervous elements, even in the deeper parts of the cortex, with increase of the supporting tissue, but in the superficial layers the degenerative and productive phenomena seemed to have come to a standstill. These changes were all fully developed at the end of thirty days, and the only further change at the end of sixty days was apparently a slight thickening of the pia. These experiments show, therefore, that the greatest changes from persistent mechanical pressure are caused in the early period. Consequently any operative interference should be undertaken as early as possible, before the nervous elements wholly disappear, in order that restitution to a healthy condition may be most likely to be obtained.

(To be continued.)

New Instruments.

A NEW THUMB SPLINT AND A NEW INTERNAL ANGULAR SPLINT.

BY VIVIAN DANIEL, M.D.,
Ex-House-Surgeon, Boston City Hospital.

WHEN we consider the relative usefulness of the thumb to the hand and its other fingers, its proper immobilization after reduction of fractures and dislocations of its bones becomes a matter of considerable importance. To this end various splints have been contrived which, however, take a great deal of time and ingenuity to make and which are difficult to keep

⁶ Deutsche zeitschrift für Nervenheilkunde, viii, 167, 1896.

in place by the ordinary means of adhesive plaster and bandage. Moreover, they are not adapted to correct bandaging, and the operator cannot satisfactorily localize his bandage pressure so that it may hold in place the reduced bones or fragments and thus correct their tendency to deformity.

A simple tin splint which seems to answer all requirements and which has been in constant and successful use at the Boston City Hospital for over a

year was devised by the writer. It can be made in five minutes by any one possessing ordinary mechanical ability, as follow:

A piece of tin varying in size according as the hand is large or small, but which for the average adult's hand should be eight inches long by four inches wide, is cut as indicated in Diagram 1, namely, from the corners A and B to the points C and D, the distance of C and D from the end E-F corresponding to the length of the thumb as measured from its web, and the space between C and D equalling slightly more than the thickness of the thumb at its base.

These cuts make for us the segments X and Z. Next bend the portion Y to slightly less than a right angle with Z with the result shown in Diagram 2. The angle thus made corresponds to that formed by the forefinger and thumb when the latter is in complete abduction.

Diagram 3 shows the next step, and is self explanatory, the tin now being moulded into two grooves, into which the thumb and forefinger are respectively to fit.

Diagram 4 shows the disposal of the parts Y and Z, these being doubled upon themselves so that when fully bent the edge A-E cuts the angle V. The

pointed ends are now turned down over the back of X and "tied in a knot." This serves to keep the thumb portion Z at the required angle with X and makes the flanges ff, which when the splint is applied form coaptation for the muscles of the ball of the

thumb. To more firmly fix our angle and make the splint as unyielding as if soldered or riveted, a small nick should be cut in the flanges ff at N and the resulting corner turned under the edge of X.

The splint is now made, and after tapping all overlying portions of tin into close apposition, it is trimmed into the shape shown in Diagram 5. Here we see the splint applied. Adhesive plaster P retains it firmly in position and crosses the back of the thumb at the seat of displacement of its bones, holding there a pad to keep them in place.

As can be seen, the splint fits like a glove and over it the most approved method of bandaging can be practised and pressure localized at will.

By making the portion Z slightly longer than the thumb and applying strips of adhesive plaster to the anterior and posterior surfaces of the latter, as shown in Diagram 5, extension can be applied and effectively maintained by turning the plaster over the end of Z and sticking it to its anterior surface.

This device constructed on a larger scale with a heavy grade of tin forms a very serviceable internal angular splint. It is made in the same way as if intended for the thumb but an additional fold is made in the flanges ff which disposes of them and at the same time strengthens the angle V. After trimming to fit the arm it is ready for use as shown in Diagram 6.

NOTE.—In making the thumb splint the portion X is likely to be longer than the forefinger; it should be shortened to suit after the first two cuts are made.

POLITICAL MEDICINE. — As there seems to be some indication that the Venezuelans are not quite prepared to consider that their difficulty with England is ended, it is of interest to note that the *Medical Age* says that "An Up North Democrat, wrote Senator Roach: 'All the fools around here are talking about the Monroe doctoring, and nobody knows what it is, and I don't know it myself; but if the government is giving it away, send me what you can.'"

Reports of Societies.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

PAUL THORNDIKE, M.D., SECRETARY.

REGULAR Meeting, Wednesday, November 4, 1896,
DR. M. H. RICHARDSON in the chair.

ANATOMICAL SPECIMENS.

DR. M. H. RICHARDSON: I wish to show first an x-ray photograph of a tumor of the thigh. It shows an interesting thing about the growth which was diagnosed osteo-sarcoma of the femur. Unlike some of the cases in which the diagnosis of osteo-sarcoma has been made, the bone is not affected or affected very little. You will see the femur passing through the tumor. There are what seem to be concentric layers of bony tissue outside the dark shadow of the femur. This amputation was performed October 21st. I have not heard from the microscopic examination.

I would like to show two specimens of the vermiform appendix I have recently removed. Although the subject of appendicitis may seem a little stale, most of us, I think, will admit that we do not know all there is to be known about it. The first is a case of removal in the interval of health. The chief symptoms were pain in the epigastrium, gradually becoming localized in the right side. During the pain the right testicle was retracted; the urine contained a trace of albumin and other things from which the urinary chemist made the diagnosis of oxaluria and chronic passive congestion. The diagnosis lay between an oxaluria or calculus in the right kidney, trouble down in the right ureter or chronic appendicitis. I operated with fear and trembling. On the whole, I thought the trouble was appendicitis. The chief reason for operating was that the man's business takes him to remote parts of this country and Europe, and I thought it would do no harm to take out the appendix the danger being so slight. We have now taken out 95 or 96 without a death.

This was a very thick, club-shaped appendix, adherent to a coil of small intestine near the bladder and adherent near the cruro-genital nerve; and I think the attacks of pain in the testicle were due to irritation of that nerve. It had to be dissected out its whole length. There was no question of the diagnosis. The diagnosis was made by Dr. Whittier and Dr. McKay.

Here is a sketch of the same, which shows the appearance accurately. That case, and the second one which is shown here, is evidence to prove the truth of the proposition that in every case in which the appendix is diseased it should be removed; I mean to say that in every case in which there has been one attack of appendicitis the appendix should be removed in the interval following that attack, as a rule. This does not apply to acute appendicitis. This young man, a coachman, nineteen, was taken eight weeks ago with an attack of appendicitis not very severe, but an undoubted attack. Night before last he was taken with severe abdominal pain, high pulse, but not an especially high temperature. The perforation was near the cecum. The abdomen was filled with turbid serum, the pelvis with sulphuretted hydrogen.

DR. PRESCOTT tells me the specimen of tumor of

the femur was malignant endothelioma starting from the lymph-spaces.

DRS. M. H. RICHARDSON and H. A. LOTHROP read a paper on

GUN-SHOT WOUND OF THE KIDNEY.

DR. J. E. GOLDTHWAIT read a paper on

THE TREATMENT OF DISABLED JOINTS RESULTING FROM THE SO-CALLED RHEUMATOID DISEASES.¹

DR. F. C. SHATTUCK: Dr. Goldthwait has well characterized these cases as "discouraging." Every one present must have deeply stamped on his memory cases of the kind which have come under his observation and many a village throughout the country has its hopelessly crippled subject of this disease, an outlet for the neighboring sympathies of the community. Almost my earliest pathological remembrance is of a case of the kind in a New Hampshire village, a bedridden woman whom, as a child, my father occasionally took me to see. The disease has long been an opprobrium to medicine, some of its victims are examples almost of living death, and this contribution of Dr. Goldthwait, showing what combined skill and patience can do, seems to me very important.

The terminology of the affection deserves a word. Arthritis deformans appears to me by far the best name in that it is eminently descriptive, carries with it no pathological theory, and conveys no suggestion of rheumatism, as do the terms rheumatic arthritis and rheumatic gout. A practical danger connected with the use of these latter terms is that thus some excuse seems to be given for the administration of anti-rheumatic remedies or procedures which, in so far as they are lowering, are apt to be distinctly harmful.

The diagnosis is well marked, indeed in most cases, is not difficult. But in some of the more acute and earlier forms of arthritis deformans the differentiation from true rheumatism may not be so easy. And we do see some cases in which the two affections are combined. There is now in my hospital ward a young woman in the seventh month of pregnancy. She gives the history of two attacks of acute rheumatism, has aortic and mitral disease and one hand shows highly typical lesions of arthritis deformans with extreme ulnar dislocation at the metacarpophalangeal joints.

The spindle-shaped swelling; the localization, pretty symmetrical in a considerable number of small joints; the persistency of the lesion which does not flit from joint to joint; the predilection for women, often young; pronounced muscular atrophy; clammy fingers and debility—these are all important diagnostic points. I have not been able to verify, perhaps from lack of experience, the observations of Spender, of Bath, who considers a quick, hard pulse and yellowish pigmentation about the forehead as premonitory symptoms.

As regards treatment, the avoidance of all debilitating agencies of whatever kind is of the last importance if we wish to delay the progress of the disease. I have thought the use of the hot sand bath for the hands, when swollen and painful with acute outbreaks, of distinct service.

I will now pass round two radiographs, one of a normal hand, the other of the hand of a young girl now under my care suffering from an acute form of arthritis deformans. The thickening about the phalangeal

¹ See page 79 of the Journal.

joints distinctly leaves the outline of the articular surfaces as compared with the normal hand. This young girl has been helpful about the ward and has thus contracted typhoid fever. She is now in the third week and it is interesting to note that the improvement in her hands, which had set in before she took the fever, has been much more rapid since the advent of the febrile process.

DR. GOLDTHWAIT: As Dr. Shattuck has mentioned the pathology I will pass around these specimens I found in the museum, which illustrate the two conditions.

DR. PAINTER: During the last two months I have been examining from the bacteriological point of view the fluids obtained by aspiration of some of these cases of rheumatoid arthritis. Though I am not prepared at present to make a report on these cases I would simply recall to those who are interested in the bacteriology of the subject and its pathology, some of the work that has been done by Dr. Blaxall in the laboratory in the Society of Preventive Medicine in England. He has examined the fluid from some 18 or 20 cases of rheumatoid arthritis referred to him from the baths at Bath, in England, and he has found in every single case a bacillus which seems to be pathogenic of the disease. He met with considerable difficulty at the beginning of the investigations. The organism did not take up the ordinary stains which were well known to the bacteriologist, neither did they grow on the culture media at his disposal, and consequently the start in the study of the bacteriology of this subject was made under considerable disadvantage. However, after repeated experimentation he found that the difficulty was in the minuteness of the organism and in the difficulty of taking up the stain due to the presence of the synovial fluid, and after modifying to some degree his ordinary method he succeeded in getting a stain with the aniline methylene blue after an exposure of some three or four days. So far as the cultural methods are concerned the difficulty seems to be in the opacity of many of the media and the very delicate growth of the organism so that he had to use very clear and rarified culture media in order to obtain a growth. After this technique had been perfected he had no difficulty whatever in cultivating the organism and in obtaining the same organism from these cultures stained by the method he had already demonstrated. So far as inoculation of animals is concerned some experiments have been undertaken which are said to go to prove that this organism injected subcutaneously into rabbits produces a disease in them, in a way analogous to the so-called rheumatoid arthritis. He also succeeded in obtaining from the blood near these joints in persons suffering from this disease the organism which he had found in the joint fluids.

DR. FITZ: I think this community ought to feel particularly grateful to a physician who like Dr. Goldthwait is willing to give his time, patience and skill to the treatment of this class of cases, especially as they occur generally among those not able to pay in proportion to the value of the services rendered.

I may be allowed a word with reference to the classification of these affections and a suggestion as to the easiest way of avoiding confusion in terminology. Dr. Goldthwait groups his cases under rheumatoid arthritis and under osteoid arthritis, but the distinction fails of support on anatomical grounds, and perhaps he will bear me out in admitting that the clinical characteris-

tics will vary somewhat in connection with the differing nature of the anatomical lesions. In the group of cases of rheumatoid arthritis there is undoubtedly bone-formation in a certain number, consequently an osteo arthritis exists, whereas in the class of cases designated osteo arthritis, deformity of the joint is so conspicuous as to call for the term arthritis deformans as suggested by Dr. Shattuck.

It seems to me desirable for the present to hold to the terms rheumatoid arthritis or arthritis deformans and rheumatic arthritis, it being of course, understood, that there is no demonstrable relation, in the great majority of cases, between what is called acute articular rheumatism and rheumatic arthritis and rheumatoid arthritis. In certain cases, undoubtedly, repeated attacks of acute articular rheumatism will leave chronic inflammatory processes in the joints affected.

The term, chronic rheumatic arthritis, is best retained for the class of cases represented by the spindle-shaped swelling in the vicinity of the joint which, in considerable part, is due as well to inflammatory exudation outside the joint as to increased quantity of fluid in the joint. This class of cases in time may result in loss of cartilage and actual obliteration of the joint by fusion of the bones, as seen more particularly in the vertebral joints. This is the class of cases occurring especially in persons under middle age, and is often associated with a great degree of immobility of the joint. It is desirable to restrict the term rheumatoid arthritis to the class of cases associated with extensive growth of cartilage and bone, often projecting as outgrowths and with eventual disappearance of cartilage and churning of bone. In these cases there is often a considerable degree of spontaneous dislocation, and perhaps the formation of false joint; and although the mobility of the joint is impaired to considerable extent, it is usually more freely movable than in chronic rheumatic arthritis. This is the variety seen more often in old people especially affected in the large joints of the body.

The pathology of these varieties of chronic joint inflammations is exceedingly obscure and the researches of the bacteriologist will be awaited with interest, although without much hope.

DR. GOLDTHWAIT: The case to which Dr. Shattuck referred and which Dr. Richardson will remember, was a man whom I saw two years ago because of ankylosis of both hips, knees and all the joints of the knees and ankles. At that time I classed the case as one of rheumatoid arthritis. In seeing him a few days ago and going more carefully into the early history of the condition I was not able to throw out the possibility of the typhoid as the cause of the trouble. He gives a history of acute sickness some few months before the joint trouble came on, and to be perfectly sure, and to eliminate all cases but those which seemed to me to be purely rheumatoid arthritis, I threw this out. The man is now well and earns his living as a travelling salesman.

CLINICAL RECORDS. — At an East-end Hospital a man was brought in terribly smashed. A new house-surgeon having examined him, said to his wife, "I fear your poor husband is dead." "No, I ain't," said the supposed corpse. "Hush, John, be quiet," said the wife, "the gentleman must know better than you what's the matter with you." — *St. Thomas's Hospital Gazette*.

Recent Literature.

The Diary of a Resurrectionist, 1811-1812. To which are added an Account of the Resurrection Man in London, and a Short History of the Passing of the Anatomy Act. By JAMES BLAKE BAILEY, B.A., Librarian of the Royal College of Surgeons of England. London: Swan, Sonnenschein & Co., Limited. 1896.

This interesting and curious little book might better be called "An Account of the Resurrection Man in London, etc., to which is added the Diary of a Resurrectionist," as the diary is printed at the end of the book and occupies less than a quarter of the bulk of the volume. The account of the resurrection man gives a vivid picture of the straits to which teachers of surgery and anatomy were put to secure a meagre and very expensive supply of anatomical material.

The book is illustrated by photographs of the mortsafes of iron and stone which were erected over graves in the cities of England and Scotland to secure their contents against riflers. The surgical teachers of that day were forced by the necessity of procuring anatomical material, to deal with these thieves and ruffians, and the price of a dead body was often as high as sixteen guineas. The teacher was often forced to go bail for his providers when arrested for body snatching, pay their fines, or support their families during their confinement in jail. Gruesome accounts of sanguinary fights between rival gangs of body-snatchers over newly-made graves are given, and many curious facts regarding this traffic in dead bodies.

The diary itself gives a laconic account of the transactions of the worthy who wrote it, including the prices paid, the teachers to whom the bodies were delivered, and the nights he and his partners got drunk. The object of such a man in keeping a diary would be interesting to know. A photographic facsimile of a page in the diary is given.

The book is handsomely printed and bound.

Recherches cliniques et thérapeutiques sur l'épilepsie, l'hystérie et l'idiotie. Par BOURNEVILLE, médecin de Bicêtre. Volume XVI, 8vo, pp. lxxi, 254. With 31 illustrations and 8 plates. Paris: Aux bureaux du *Progrès Médical*. 1896.

Beside the usual reports and statistics of the service of idiotic, epileptic and backward children at Bicêtre during the year 1895, the present volume contains a considerable number of clinical and pathological reports. Several cases are reported of idiocy due to meningitis of various forms. In one case of microcephalic idiocy, double craniectomy was performed without notable improvement in the mental condition. Among the cases of greatest interest are those of myxedematous idiocy, due to congenital absence of the thyroid gland, considerably benefited by the ingestion of sheep's thyroids into the stomach after the administration of thyroid juice and the subcutaneous injection of liquid thyroid had proved ineffectual.

"MODERN GREEK AS THE UNIVERSAL LANGUAGE," is the title of a paper by Dr. Franklin Bache Stephenson, U. S. Navy, which appeared in the December, 1896, issue of *The Alleghany Literary Monthly*, published at Meadville, Penn.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JANUARY 28, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE COMPULSORY NOTIFICATION AND ISOLATION OF PULMONARY TUBERCULOSIS.

IN last week's JOURNAL (p. 74), an abstract was given of a supplementary report on the subject of pulmonary tuberculosis, made to the New York City Board of Health by the pathologists of the Board, Drs. Biggs and Prudden. A previous report had been rendered in November, 1893.

As a result of this supplementary report, the Board of Health, at a meeting held January 19th, enacted an addition to the Sanitary Code, which officially declares pulmonary tuberculosis an infectious and communicable disease. The new section of the code prescribes that it shall be the duty of every physician in the city of New York to report to the Sanitary Bureau the name, age, sex, occupation and address of every person suffering from this disease, who has come under his observation for the first time, within one week of such time. Also, that it shall be the duty of the authorities of every public or private hospital or dispensary to report in the same way every case treated in such institutions. Finally, that it shall be the duty of every person with this disease, and of every person in attendance on such cases, and of the authorities of public and private institutions, to observe and enforce all the sanitary rules and regulations of the Board of Health for preventing the spread of pulmonary tuberculosis. The new law renders physicians and laymen alike liable to punishment for misdemeanor when any part of the section is violated. An important feature of the law also provides for the isolation of patients in aggravated cases.

In order to facilitate the restriction of tuberculosis, the Board of Health has ordered the preparation of a map, showing every house in which there is a case of the disease, and also every house in which a death has occurred from it.

Following this extension of the Board of Health's Sanitary Code, at a meeting of the New York Academy of Medicine, held January 21st, Dr. Irwin H.

Hance read a paper entitled, "A Further Study of Tubercular Dust." The paper was based upon experiments made by the reader at the request of Dr. Biggs. Dust was collected in hospitals, dispensaries, tenement-houses and public conveyances, and healthy guinea-pigs were inoculated with a solution in which it was introduced. Three out of four guinea-pigs inoculated with dust taken from a tenement-room in which a phthisical woman had lived and died, died with well developed tuberculosis; while four guinea-pigs inoculated with dust taken from a room where a patient with tuberculosis lived, but who observed the regulations of the Board of Health showed no sign of disease. At the end of 57 days the animals were killed, and no trace of tuberculosis was discovered in them.

As to the dust collected from street-cars, of sixteen guinea-pigs inoculated with dust from dirty places, five died; of twelve inoculated from clean places, two died. Five more when killed showed signs of tuberculosis. One in five cars examined was found dangerous to the health of the travelling public.

Having demonstrated the existence of tubercular dust in the waiting-room of a dispensary, Dr. Hance went on to say: "The proof of its existence in this one case, demands greater care on the part of the managers of such institutions, where so many children are brought to be treated for other diseases, and while waiting their turn, subjected to a real danger." In speaking of tenement-houses, he said: "The result of the experiments shows that the seeds sown by the Board of Health are bearing fruit. All the cleanly apartments were found free from infection. This proves the wisdom of granting the Board of Health power and authority to order such cleaning and renovation of tenements as is required."

This question of compulsory notification and official supervision of pulmonary tuberculosis was discussed at much length at a special meeting of the College of Physicians of Philadelphia, called for the purpose in January, 1891. Its adoption was opposed at that time by several physicians to whose opinions much weight must be given.

The provisions lately adopted by the New York City Board of Health are undoubtedly in a measure revolutionary, and may, we fear, prove somewhat extreme and in advance of public and of medical opinion.¹ We cannot but think, however, that they are in the line of future progress in the application of medical and sanitary science.

Laws are only useful in so far as they can be enforced and enforced with less loss and injury than is entailed by their absence. The useful and possible enforcement of the regulations under discussion will depend very greatly upon the tact, discretion and good judgment of those entrusted with carrying them out. The working and the results of these regulations in New York will be watched everywhere with much interest.

Pulmonary tuberculosis is only one of several im-

portant diseases in which the bacteriological laboratory is invading the former domain of the clinical practitioners. Diphtheria is another. The question of diagnosis, of isolation, of treatment in the large sense, is decided to-day in the laboratory rather than at the bedside. There is a danger of being too ready with these new-found weapons, of expecting too much from them; but there is also the danger of rejecting them because they are new. The general practitioner may be a very desirable check upon the enthusiastic bacteriologist, but the practitioner, the hospital clinician, the bacteriologist, should all co-operate cordially and heartily together and carry the general public along with them by example as well as by precept.

There is work for all, and distinction to be gained from good work by all, but there should be no room for jealousy and no time for hindrance.

RABIES IN ENGLAND.¹

THE British Board of Agriculture has issued a report of their proceedings, under the Diseases of Animals Acts, for the year 1895, in which considerable information relative to the prevalence of rabies will be found interesting to medical men. Tables are presented and a colored map indicating the comparative prevalence in different counties. Lancashire and the West Riding of York appear to have been the most seriously affected.

The animals attacked with the disease were dogs, cattle, sheep, swine, horses, deer and cats, but mostly dogs. The number of dogs attacked in the past eight years was as follows: 1888, 160; 1889, 312; 1890, 129; 1891, 79; 1892, 38; 1893, 93; 1894, 248; 1895, 672. Out of this large number in 1895 (672) 273 were said to be stray dogs, that is, dogs which, during the time when they were affected with rabies, had wandered into districts remote from their homes.

Previous reports had shown that it was this particular class of dogs which perpetuated rabies; and as it is quite impossible to prohibit or regulate the movements of dogs in the same manner as other animals, it is obviously hopeless to expect that the disease can be suppressed unless measures are universally adopted for the seizure of all ownerless dogs.

In 1889, with the view of checking the progress of this terrible disease and possibly of extinguishing it in the districts where it was prevailing, orders were passed imposing the muzzle upon dogs in those districts. Local authorities and dog owners protested loudly, and the general public appeared altogether indifferent; but the Board, in the face of persistent opposition, maintained the order in the affected districts till 1892, when, in deference to the generally expressed wishes of local authorities, the order was finally withdrawn, leaving further action in the hands of each local authority. The measures taken by the Board,

¹ Editorial in *Journal*, May 28, 1896; also, "Prevention of Tuberculosis," *Jas. B. Russell, M.D.*, Glasgow.

¹ Annual Report of Proceedings under the Diseases of Animals Acts of 1894, etc., pp. 110. London, 1896.

however unpopular at the time, had materially decreased the amount of the disease, and as a result the number of cases among dogs had fallen in 1892 to 38. After the withdrawal of the order, the number of cases increased more than seventeenfold, the number reported in 1895 being 672. *

The Board further says: "There can be but little doubt, and it can hardly be too often repeated, that, if in every instance where a dog has been certified to be rabid, all other dogs that have in any way been associated with the diseased animal were as far as possible traced and promptly destroyed, and the requirement of the muzzle was strictly enforced over a wide area for a period of, say, six months, the disease need never become prevalent; and if these measures could be accompanied with effective precautions to prevent the re-introduction of the disease from abroad there seems no reason to suppose that the dire scourge might not within a moderate period be entirely eradicated from the country."

It is instructive to compare with this weak and vacillating policy of the British authorities, the rigorous muzzling measures now pursued in Berlin where hydrophobia is consequently entirely suppressed.

MEDICAL NOTES.

MORTALITY FROM PLAGUE AT BOMBAY.—The latest report from Bombay places the total mortality up to date, from plague in that city, at 10,000.

PRECAUTIONS AGAINST PLAGUE.—As a result of the conferences held by the Imperial board of health upon the question of the bubonic plague in Bombay, German health officials have been sent to Vienna and Rome to arrange preventive measures against the introduction of the disease into Europe.

AN ENORMOUS FIBROID TUMOR.—At the November meeting of the Section on Gynecology of the College of Physicians of Philadelphia, Dr. C. B. Penrose reported an operation for the removal of an edematous fibroid tumor of the uterus, weighing eighty-seven pounds. The patient died four hours after the operation, probably from sudden relief of pressure upon the vascular system. — *American Journal of Obstetrics.*

THE GERM OF YELLOW FEVER.—It is stated in a dispatch to the *London Times* that a young Italian physician, Dr. Guiseppe Santarelli, of Montevideo, now director of the Uruguayan National Institute of Experimental Hygiene, has discovered the microbe of yellow fever. He was led to investigate the subject by passing through an attack of the disease himself at Rio de Janeiro. A description of the microbe found has been sent to the Royal Academy of Medicine, Rome.

UNPAID DOCTORS' BILLS.—The British Medical Protection Society, among other duties, undertakes the collection of over-due fees and accounts of its members. During the past five years application for the overdue fees of the members have been made, amounting in all to a sum of no less than £46,376 12s. 6d. Of

this amount, £25,870 5s. 6d. was collected without the necessity of resorting to legal compulsion. But even the first named immense sum, as the *Medical Press and Circular* remarks, cannot represent probably more than a proportional part of the unpaid indebtedness of the public to the British medical profession, for it is hardly to be supposed that each member of the profession, to who is owed fees which he cannot obtain, is a member of the British Medical Protection Society. In this country physicians have no such means either of having bills collected for them, or arriving at an estimate of their total amount; but there is every reason to suppose, on the basis of individual experience, that the proportion of unpaid bills to the total is as great in America as in Great Britain.

FOUND DRUNK.—When the police in Denmark find any one in the streets drunk and incapable they take him in a cab to the station, where he gets sober under a surgeon's care. On recovering sobriety the police take him home. A bill for the services of the cabmen, the surgeon, and the police agents for special duty is then presented to the host of the establishment where the patient took his last drink. In Turkey, if a Turk falls down in the street while intoxicated and is arrested, he is sentenced to the bastinado, which punishment is repeated as far as the third offence. After the third bastinadoing he is considered to be incorrigible, and is called "Imperial," or "privileged" drunkard. If arrested after that he has only to give his name and address, and state that he is a "privileged" drunkard, when he is released and conducted home, the bill for these kindnesses being rendered to him for payment next day. — *British Medical Journal.*

SURGEON-MAJOR PARKE.—A memorial statue of Surgeon-Major Parke, who, it will be remembered, was the surgeon of Stanley's African expedition, has recently been unveiled in Dublin. In commenting upon the occasion the editor of the *Medical Press and Circular* pays this tribute to the character of Parke, whose devoted, unselfish and untiring service to the members of this expedition won for him the respect and admiration of his nation: "No man, as we believe, courted notoriety less than he, no man gave himself less trouble to push for promotion, and no man made less effort to acquire expertness in the blowing of his own trumpet, an accomplishment to which many, if not most men, owe their progress in life. Moreover, when he had achieved honor and celebrity, was flattered by every one and petted by great people, his modest and ingenuous spirit rose superior to the weaknesses which such conditions commonly bring out. The superiority of manner and condescending drawl assumed and improved upon by the ordinary pushing self-seeker were not found in Parke, nor had he occasion to clear the way for further advancement by kicking down the ladders which had raised him. He was a gentleman in mind and a hero in spirit, and the testimony of his nation's approval and admiration was well-deserved."

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, January 27, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 126, scarlet fever 43, measles 97, typhoid fever 8.

A NEW DISPENSARY. — The new dispensary of the New England Hospital for Women and Children, at No. 29 Fayette Street, Boston, was opened to patients on January 25th.

BOSTON CITY HOSPITAL CLUB. — The annual meeting of the Club will take place at Young's Hotel, Boston, on the evening of Wednesday, February 3, 1897, at half-past five o'clock. The annual dinner will follow immediately upon the adjournment of the business meeting.

THE BOSTON LYING-IN HOSPITAL. — At the annual meeting of the trustees of the Boston Lying-in Hospital, which was held last week, all the officers were re-elected. The trustees' report showed that in the last year 2,242 patients in confinement were taken care of by the hospital staff, being 224 more than in 1895, and 678 of these were cared for in the wards of the hospital. The percentage of deaths was less than one-half of one per cent. Nineteen nurses received diplomas during the year, and six physicians received the hospital training. The expenses of the hospital were more than \$20,000. These expenses have to be met in large measure by voluntary contributions and subscriptions, and more money is needed, as the work increases from year to year. Subscriptions for a larger amount will be needed this year, if the hospital is to continue its valuable work, and such may be sent to George von L. Meyer, Treasurer, 89 State Street, Boston, or to the hospital, 24 McLean Street, Boston.

SUITS FOR POISONING BY GELSEMIUM. — Two suits are in progress before the Superior Court, at Worcester, against a "cancer doctor," who has an office in Boston, one to recover \$1,025 paid him by Joseph A. Battles, of Fitchburg, for medical attendance upon his wife, and another for causing the death of the latter by negligence and unskilful attendance. Drs. Hitchcock and Fish, of Fitchburg, who were called to attend Mrs. Battles just before her death, found her in a collapse, and found a medicine bottle in the room, the contents of which proved, on analysis by Dr. Edward S. Wood, of Boston, to be a preparation of gelsemium. The accused had been treating Mrs. Battles for cancer since last March.

NEW YORK.

THE FIRE AT BELLEVUE. — The building occupied by Bellevue Hospital Medical College, situated within the grounds of the hospital, was severely injured by fire on January 20th. The entire upper portion of the building was destroyed, and the lower portion so completely flooded with water that all it contained was ruined. Much valuable apparatus and many rare specimens were lost. There was a marked ab-

sence of excitement among the patients of the hospital, and the strictest order was maintained throughout. The lectures of the college will be continued in the Carnegie Laboratory Building, across the street, which was not reached by the fire.

PRECAUTIONS AGAINST PLAGUE. — Health Officer Doty has made application to the Legislature for a special appropriation of \$5,000 to carry out precautions against the entrance of the plague into this country through the port of New York. In the meanwhile Dr. Joseph N. Senner, Emigration Commissioner, has accepted from the United States Government the disinfecting plant erected at Sandy Hook at the time of the cholera outbreak in 1892, at a cost of \$75,000, and is now making arrangements for the transfer of the apparatus to Ellis Island.

RECORDER GOFF'S GRACIOUS ALLUSION TO MEDICAL EXPERTS. — The annual banquet of the Medico-Legal Society was held at Hotel Marlborough on January 20th. Among the speakers was Recorder Goff, who made a violent attack upon medical experts, whom he kindly characterized as "mountebanks and charlatans."

DEATH AT ONE HUNDRED AND EIGHT YEARS. — Alexander Freeman, a negro, died at Sailors' Snug Harbor, Staten Island, on January 22d at the reputed age of 108. He was a native of New York City, and there is reason to believe that the extreme age given is not an exaggeration.

ANNUAL REPORT OF THE POST-GRADUATE HOSPITAL. — The twelfth annual report of the New York Post-Graduate Hospital, just published, shows that during the year 1,895 new house patients were treated. Of these, 729 were infants, and 1,166 children and adults. The increase in the number of patients over the previous year was 160; 20,084 patients were treated in the dispensary, to which 75,153 visits were made; and the district physician attended 527 patients at their homes.

A CLERGYMAN VIOLATES THE HEALTH LAWS. — The Dutchess County Grand Jury has indicted the Rev. George D. Silliman, rector of a prominent Episcopal church in Albany, for wilful violation of the health laws, in removing his sick son from St. Stephen's College at Annandale in defiance of the quarantine established by the Health Officer Dr. H. L. Cookingham, of Red Hook. The son, while a student at the college, was on December 5th attacked with diphtheria. The diagnosis, made by the local physician in attendance, was accepted by Health Officer Cookingham, who closed the college, isolated young Silliman, and quarantined the rooms. The quarantine was maintained for a week, when Dr. Silliman came from Albany and asked permission to take his son home. Notwithstanding that the request was refused, he hired a carriage and conveyed the young man to the neighboring station at Barrytown, on the Hudson, whence he travelled with him by train to Albany.

Miscellany.

THE LABORDE METHOD OF RESUSCITATION.

AN experimental study of the method of resuscitation by rhythmical tractions on the tongue, which was advocated by Dr. Laborde about a year ago as an effective method in cases both of submersion and collapse during anesthesia, and was the subject of much discussion at the French Academy of Medicine, has been made by Dr. Haubold, of New York.¹

Five experiments were tried. In the first, which may be considered a severe test of the method, a dog was quickly killed by a large amount of chloroform, and as soon as the heart had stopped beating, rhythmical tractions on the tongue were begun, and continued for two hours, with a negative result. The second experiment was the submersion of a dog in the water for fifteen minutes. The dog ceased struggling after a minute and ten seconds. Traction on the tongue for two hours failed to revive him. In the third trial two dogs were submerged for three and one-half minutes. One was left to himself, and the other, after two minutes had elapsed, was subjected to rhythmical tongue traction as before. The fourth experiment was practically a repetition of the preceding, and was also negative in its result, although both dogs struggled to within fifteen seconds of the time they were removed from the water, and muscular tremor was present for some minutes after they had been removed, indicating, perhaps, that very little stimulus to the heart or respiration would have been sufficient to cause functional activity.

In the fifth experiment an attempt was made to imitate the conditions present in an accidental death from inhalation of chloroform for anesthesia. A dog was chloroformed until anesthesia was produced, and then the chloroform was increased until respiration ceased, and then removed. The heart was still acting, and continued to act more or less irregularly for one minute and forty-five seconds after the removal of the drug. Tongue tractions were continued for an hour with no result whatever. The writer sums up his experiments as follows:

"It will be seen from the foregoing observations that the method of resuscitation was given tests of considerable variance as regards severity. While it is true that in Experiment I a large amount of chloroform was administered, and in Experiment II the animal was submerged for fifteen minutes (a considerable period of time), still, in face of the contention by Laborde that persons that have been submerged for an hour have been resuscitated by this method, these tests would seem to be fair enough. But further than this, it will be seen that in Experiments III and IV the animals were submerged for three minutes and a half, and then left to themselves for two minutes, making a total of five minutes and a half only, and still resuscitation was not achieved. Indeed, in Experiment IV there was the muscular tremor already alluded to; surely here resuscitation should have been successful. And last of all, Experiment V, it seems, can well be called a fair test. Without recapitulating the entire observation, attention is called to the fact that tongue tractions were begun *immediately* after the heart ceased acting, and that no time was allowed to elapse as in the other observations. As a matter of

fact, the observations here recorded leave little doubt that the Laborde method of resuscitation leaves much to be desired, and that it is not to be employed to the exclusion of the other methods now in use.

THERAPEUTIC NOTES.

FORMALIN AN APPROXIMATE SPECIFIC FOR RINGWORM.¹—An interesting editorial note has appeared in *Guy's Hospital Gazette* calling attention to a recent paper by Mr. Alfred Salter, on the treatment of ringworm by formic aldehyde, or formalin. This treatment is now so well known in Guy's, and has had such a conspicuous success, that it should be part of the ordinary practice of every old Guy's man. There seems no doubt that it is the almost specific treatment for the disease, especially in obstinate and hitherto incurable cases. And yet this discovery arose from the annoying fact that the inventor's cultivations of the ringworm microbe were all killed one night through his having left the stopper out of the formalin bottle.

FOR DYSPEPSIA AND VOMITING IN TUBERCULOUS SUBJECTS.²—Dr. Barth recommends this formula:

R	Prepared chalk,	} āā	3.	grains.
	Calcined magnesia,			
	Manganese dioxide,		1.5	grains.
	Powdered belladonna		.15	grains.

M. For one dose, to be taken after eating. If there is severe pain, .15 of a grain of powdered opium may be added.

THE TREATMENT OF PHRENO-GLOTTIC SPASM IN SUCKLINGS.³—Vergniaud gives a drop or two of chloroform by inhalation during the spasm, and prescribes the following:

R	Tincture of musk	20	drops.
	Tincture of belladonna	10	drops.
	Cherry-laurel water	120	grains.
	Syrup of orange	300	grains.
	Lactucarium water	1,500	grains.

M. S. Five or six teaspoonfuls to be taken twice a day.

NEPHRITIS.⁴—Pulvirenti gives ergotin in the following prescriptions:

R	Ergotini	5	gm.
	Ac. gall.	8	gm.
	Extr. et pulv. rad. ratanh. q. s. ut ft. pil. tr. viginti.		
S.	Take one pill four times a day.		
R	Ergotini	2.	gm.
	Ac. gall.	4.	gm.
	Saccharini05	gm.
	Muc. gumm. arab.	200.	gm.
M. S.	Teaspoonful twice a day.		

A PRESCRIPTION FOR ATONIC ULCERS.⁵

R	Iodol	2	parts.
	Vaseline, } āā	10	parts.
	Lanoline,		

M. To be spread thin on aseptic lint and applied.

FACIAL ERYSIPELAS.⁴

R	Acid Carb. } āā	2.0	gm.
	Tr. Iodi,		
	Alcoh. abs.	4.0	gm.
	Ol. Terebinth	6.0	gm.
	Glycerini		

M. D. S. External use. Wash the affected parts with the mixture every two hours.

INFLUENZA.⁶—Pepper recommends

R	Quin. Sulph.	3.0	gm.
	Pulv. Igit. } āā	1.0	gm.
	Pulv. Scill.		
	Extr. Op.	0.3	gm.
	Extr. Glycyrrhize q. s. ut ft. pil. tr. triginta.		

S. Take one pill four times a day.

Correspondence.

GLION, CANTON VAUD, AS A HEALTH-RESORT.

PARIS, January 10, 1897.

MR. EDITOR:—In these days when health-resorts are a necessity to the invalid, I should fail in my duty if I did not bring to the notice of physicians the village of Glion in Switzerland.

Glion is situated 900 feet above Montreux in the Canton Vaud on Lake Geneva, and lies 2,270 feet above sea-level. The beauty of the outlook from this charming spot is very unusual in its exquisite variety. Experienced travellers unite in the opinion that the scenery about Glion is more picturesque than that of any other place in Switzerland. Walks about Glion are so numerous that the pedestrian cannot soon exhaust their delights. Every direction gives one a new and fascinating combination of lake, snow, mountain, forest, stream, field and garden. Walks through dense pine woods are a special benefit.

There are several hotels and pensions which will satisfy any purse, whether plump or lean; but the hotel to be most highly recommended is the "Victoria" kept by Küpler Brothers. The unexceptionable table, cleanly rooms, excellent beds, pure drinking water, scientific drainage, good service, circulating library, tennis court, billiard room, a daily orchestral concert, evening dances and amusements leave nothing to be desired. One can live at this hotel at rates not exceeding fourteen and averaging from eight to ten francs per day. It has an immense piazza sheltered by awnings for sunny weather. Another piazza, 150 feet in length, has a roof and abundance of easy chairs. Being open to the air upon one side and looking out upon a fine garden, it serves admirably for promenades or for an air-bath during rainfall. It is here that the excellent orchestral concerts are given.

A striking peculiarity of Glion is the quality of the air, not merely because it is pure and sweet in the ordinary sense, but because of its extraordinary cleanliness. It is then almost superfluous to point out what refreshment and purification one's blood undergoes during a stay of weeks in this delicious air.

Many a neurasthenic invalid has become vigorous in Glion and a chief incentive to this letter is the value of the Glion climate in this class of cases. A gradual and certain increase of vigor, of moral tone, of objective interest, of normal appetite and nightly sleep is the result of a summer spent in Glion. Tranquillity replaces psychical unrest. The daily walk is prolonged without undue fatigue and a day arrives when the former invalid is surprised by the discovery that a comparison of present with former conditions shows that she has become another and a healthier creature.

Glion has done much, also, for weak and faulty digestion. Cases of chronic dyspepsia and of irritable stomach are sent to Glion, with the logical expectation that health will be restored, and this hope is usually realized. The physicians of Aix-les-Bains, after their patients have completed a course of baths, send them to Glion to complete their cure. A need of refreshment, of restoration from fatigue and the effects of overwork would naturally meet with full satisfaction in this admirable climate.

Weather in Glion is much like weather in other elevated places in Switzerland. There is sometimes more rain than one would wish, and there are cool days; but, upon

the whole, visitors are perfectly satisfied with all meteorological conditions, for compensations are manifold. The roads are so hard and so few of them are level that walking is agreeable almost directly after a fall of rain.

Caux and the Rochers de Naye are places situated several hundred feet above Glion, which is connected with these resorts by a railway. Each of them possesses a good hotel and a superb view. They serve as points of interest for excursionists but do not offer the attractions to be found in Glion, nor are they equally favorable for the classes of cases which I have mentioned.

In order to reach Glion a ticket should be taken for Territet, the station at which passengers for Glion should leave the train or lake steamer. If tickets be purchased at a long distance from Territet it may be that none for this place can be obtained. In that case a ticket for Montreux will answer. Montreux lies only five minutes from Territet and the supplementary fare of a few centimes may be paid on the train. In any case, however, the traveller should insist upon having his trunks checked to Territet. Approaching by steamer there is no trouble of this nature.

Having left train or steamer, one crosses the street and takes a car by the funicular railway for Glion. Upon his arrival he will find at the station a porter from the "Victoria" to which he walks in four minutes, his luggage following upon the hotel wagon. To go to Glion in June would not be too early and unless one be very sensitive to cool mornings and evenings the invalid may remain until September 30th.

H. O.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JANUARY 16, 1897.

Cities.	Estimated population.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JANUARY 23, 1897.

H. LAMOTTE, assistant surgeon, detached from treatment at Naval Hospital, Philadelphia, and ordered before retiring board, Washington, January 26th, then home and placed on waiting orders.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE FIFTEEN DAYS ENDING JANUARY 15, 1897.

BAILHACHE, P. H., surgeon. Detailed as chairman, Board for examination of officers for promotion and candidates for appointment as assistant surgeon. January 4, 1897.

STONER, G. W., surgeon. Detailed as member, Board for examination of officers for promotion and candidates for appointment as assistant surgeon. January 4, 1897.

KALLOCH, P. C., passed assistant surgeon. Detailed as recorder, Board for examination of officers for promotion and candidates for appointment as assistant surgeon. January 4, 1897.

COPER, L. E., assistant surgeon. Relieved from waiting orders and directed to proceed to San Diego, Cal., and assume command of Service. January 11, 1897.

GARDNER, C. H., assistant surgeon. To report at Bureau, February 3, 1897, for examination for promotion. January 6, 1897. Granted leave of absence for fifteen days on completion of examination for promotion. January 11, 1897.

BLUE, RUPERT, assistant surgeon. To report at Bureau, February 3, 1897, for examination. January 5, 1897.

OAKLEY, J. H., assistant surgeon. To report at Bureau, February 3, 1897, for examination for promotion. January 5, 1897.

SPRAGUE, E. K., assistant surgeon. To report at Bureau, February 3, 1897, for examination for promotion. January 5, 1897.

PROCHAZKA, EMIL, assistant surgeon. To report at Bureau, February 3, 1897, for examination for promotion. January 5, 1897.

SOCIETY NOTICES.

MASSACHUSETTS MEDICO-LEGAL SOCIETY.—The next regular meeting will be held at the Medical Library, 19 Boylston Place, on Wednesday, February 2d, at 12 M.

Attorney-General H. M. Knowlton and U. S. District Attorney Sherman Hoar will address the Society on "The Duties of a Medical Examiner."

Dr. William F. Whitney will read a paper on "Identification of Seminal Status."

The members of the profession are cordially invited.

JULIAN A. MEAD, M.D., Secretary.

THE SUFFOLK DISTRICT MEDICAL SOCIETY, SURGICAL SECTION.—The Section will meet at the Medical Library, 19 Boylston Place, on Wednesday evening, February 3, 1897, at 8 o'clock.

At 8 P. M., "The Treatment of Old Dislocations of the Shoulder-Joint," by F. B. Lund, M.D.

At 8.20 P. M., Discussion by Drs. C. B. Porter, J. W. Elliot and G. H. Monks.

At 8.50 P. M., Presentation of pathological specimens by Prof. W. T. Councilman.

At 9.10 P. M., "Sprains and their Treatment," by Douglas Graham, M.D.

At 9.30 P. M., Drs. R. W. Lovett and J. G. Mumford will also read short (five to ten minutes) papers on this subject.

Discussion. PAUL THORNDIKE, M.D., Secretary.

TRI STATE MEDICAL SOCIETY OF IOWA, ILLINOIS AND MISSOURI.—The fifth annual meeting of the Society will meet in St. Louis, April 6, 7 and 8, 1897. A large number of valuable papers will be read. Dr. Joseph Price, of Philadelphia, will hold the Surgical Clinic, Dr. James T. Whitaker, of Cincinnati, the Medical Clinic, and Dr. Dudley Reynolds, of Cincinnati, the Dr. G. Frank Lydston, of Chicago, will entertain the members with an original story during one of the evening sessions.

G. W. CALE, JR., M.D., Secretary,
4403 Washington Boulevard, St. Louis.

RECENT DEATH.

CHARLES A. STARK, M.D., died at Marshfield, Mass., January 22d, aged thirty-five years. Dr. Stark was a native of Manchester, N. H., and a graduate of the Dartmouth Medical School. He was for a time connected with the staff of the New Hampshire Insane Asylum, and then went South, practising his profession in Louisiana and holding the post of division surgeon on the Illinois Central Railroad. In 1889 he was compelled by failing health to return to the North and in the following year established himself at Marshfield, where he acquired an excellent practice. He only gave up active practice when the progress of his last illness enforced retirement. He married, in 1886, Miss Harriet O. Walker, of Chelsea, who, with a son, survives him. He was a great-great-grandson of General John Stark. Dr. Stark was a member of the Massachusetts and New Hampshire Medical Societies.

INSOLATION.¹

BY HENRY JACKSON, M.D.,

Assistant Visiting Physician of the Boston City Hospital.

DURING the heated term of last August it was my good fortune to have under my care at the City Hospital several cases of insolation; as they offered many points of interest to me, I feel that a short discussion of the subject may not be out of place in this Section.

The common terms "sunstroke" and "insolation" (derived from the verb "insolate," meaning to expose to the rays of the sun) are not wholly appropriate, as many cases of the most severe forms of this disease are developed in persons exposed to great heat in attics or overheated rooms, though entirely shielded from the direct rays of the sun. The term "thermic fever," though etiologically more comprehensive, is not in common use in our city, and I therefore choose the word "insolation" as the title of my paper.

As the result of exposure to severe heat, we may have two different diseases produced, namely, heat exhaustion and thermic fever.

The cases of slight prostration, headache and malaise produced by heat may be classified as the mildest types of heat exhaustion. During the hot week many persons that had been overcome by heat were brought to the hospital in the police ambulance; yet they were perfectly conscious, had a normal temperature, and after a short period of rest were allowed to go home, as their symptoms were not sufficiently severe to warrant their admission considering the overcrowded condition of the hospital. Several cases were admitted that were unable to leave the hospital on account of severe headache, dizziness and exhaustion, though when they reached the hospital, at all events, their temperature was not elevated.

As the result of exposure to heat, profound collapse, with loss of consciousness and relaxation of the whole muscular system, may be seen. In such cases the temperature is subnormal and the pulse rapid. The condition is comparable to profound collapse as seen in serious surgical accidents. I have not had any experience with cases of this form, though Dr. H. C. Wood speaks of this form of heat exhaustion as not uncommon in Philadelphia. The treatment suitable for cases of collapse from exposure to heat is the same as that for collapse from any other cause, namely, vigorous stimulation and the application of heat externally.

A third form of disease, the result of exposure to great heat is described, namely, a continued fever which may simulate typhoid fever. Dr. Guiteras has especially called attention to this disease, and expressed the opinion that many cases of so-called typhoid fever in Florida are really cases of insolation of this type. I report to-night one case of continued fever that I believe was due to the results of long exposure to great heat.

In summary, then, we may say that, as a result of exposure to excessive heat, we may have four distinct diseased conditions:

- (1) Exhaustion, with normal temperature.
- (2) Collapse, with subnormal temperature.
- (3) Intense fever combined with furious acute symptoms.

(4) A continued fever with symptoms suggesting a continued fever similar to typhoid.

In 1895 Dr. C. F. Withington published a valuable paper on "Heat Prostration" in the sixth series of the Medical and Surgical Reports of the Boston City Hospital. In this paper he analyzed one hundred cases. Two-thirds were the result of exposure to the direct rays of the sun, and one-third to exposure to indirect heat. In the latter class were included workers in sugar refineries, iron foundries, bake-shops, furnace-rooms and stables. Of the 100 cases, 28 died and 72 recovered. In this series the highest recorded temperature was 111.5°, and the highest temperature with recovery 109.5°. In 84 cases there was loss of consciousness, and convulsions in 30. Dr. Withington noted that the pupils did not respond to light and were usually contracted, though at times dilated. This accords with the statements usually found in the text-books, though in all my severe cases, with a single exception, the pupils were contracted to a pin-point size. A secondary rise of temperature after the fever had been reduced by cold was not unusual. Of great practical importance is the fact that in the cold bath there may be a fall of temperature to a point far below normal, accompanied by symptoms of serious collapse. Therefore in using a bath the rectal temperature must be taken frequently; and when the thermometer registers 102° the patient should be removed from the bath, as the temperature usually continues to fall after the patient has been returned to his bed. In six autopsies quoted by Dr. Withington the chief pathological lesions were sub-endocardial and pulmonary hemorrhages, hyperemia and edema of the meninges, and a fluid condition of the blood as a whole.

Through the kindness of my colleague, Dr. Sears, I am able to report 22 cases that entered our two services: 18 men, three women, and one boy of fifteen years.

METEOROLOGICAL RECORD.

According to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps, August 6-13, inclusive:

Date.	Cases	Thermometer.			Relative humidity.			Weather.	
		Daily mean.	Maximum.	Minimum.	8.00 A. M.	8.00 P. M.	Daily mean.	8.00 A. M.	8.00 P. M.

T...13	2	76	81	70	74	79	76	Fair.	Fair.

One case entered some time after the heated term had passed by, the case of continued fever.

Eleven of the cases were mild; 10 were severe, with hyperpyrexia; and one was the case that I have mentioned as belonging to the type of continued fever due to heat. Seventeen of the cases were the result of direct exposure to the rays of the sun, and five were prostrated by indirect heat. Of the latter, three

¹ Read before the Clinical Section of the Suffolk District Medical Society, November 18, 1896.

were laundresses, one a baker and one a stableman who was working in the loft of a stable on Portland Street. Two of the severe cases suffered from indirect heat.

Five of the 22 cases died, namely, 50 per cent. of the cases severe enough to warrant one to make an unfavorable prognosis, 11 of the cases being evidently of a mild type.

Two of the cases entered on the fourth day of the heated period, five on the fifth and 12 on the sixth day; two were entered on the morning of the seventh day, but properly they should etiologically be entered as belonging to the sixth day, as they were both night-workers and were brought in in the early morning, after the temperature had been already lowered by a fresh east wind.

It is evident from this list that the ultimate cause of the prostration is to be found rather in prolonged heat than in the excessive heat of a single day. Most of the cases entered two days after the acme had been reached. These data are in accord with our practical experience that sunstrokes are not usual as the result of one or two days of excessive heat such as usually occur every summer.

During this period the humidity was not high and the weather was clear; the same may be said in a general way of Dr. Withington's series of cases. They did not occur in weather with a relatively high humidity. In Germany where sunstroke is rare amongst civilians, soldiers are not infrequently overcome by the heat during forced marches, or in military manoeuvres during hot, moist weather when the soldiers are burdened by heavy clothes and knapsacks. I remember Kussmaul said that he had not seen sunstroke except under such conditions.

The cases which I have to report I divide as follows: Mild, eleven cases, five without fever and six with low temperature; ten severe cases, with hyperpyrexia; one case continued fever.

FIVE CASES WITHOUT FEVER.

One of these cases was unconscious on entrance, two were conscious though dazed, one complained of severe headache and dizziness, and one was simply exhausted. In none of the cases were the pupils contracted, nor was there in any of them any loss of pupil reflex. One of the cases complained of abdominal pain, and had cramps in the hands. In all, the conjunctivæ were congested. In four of the cases where a history was obtained prodromal symptoms of lassitude, prostration, headache, and, in two instances, fainting, had preceded the extreme depression which caused their removal to the hospital. In only one case was there a distinct history of a cessation of sweating before the onset of more unfavorable symptoms. One had worked in a bake-shop on the last hot night of the series, and fainted twice before he was brought to the hospital with a normal temperature, though no baths had been given outside of the hospital.

All left the hospital in two or three days apparently well.

SIX CASES OF MODERATE FEVER.

Four of these cases were perfectly unconscious on entrance; while two were semi-conscious, though much dazed and roused only with difficulty. In five of the cases the pupils were equal and reacted perfectly; in one the pupils were contracted. In all the conjunctivæ were injected. Prodromata were more

marked than in the preceding series. One had complained of vomiting and marked prostration for two days before the onset of unconsciousness; three had severe headache and general malaise; again, one only noted and spoke of a cessation of sweating. The range of temperature was from 100° to 104°; in all there was a slight elevation of temperature on the second day, the temperature being normal on and after the third day. In the case with contracted pupils there was retraction of the head, and an occasional convulsion of the whole body. In the other cases no untoward symptoms were noted except moderate headache and weakness. The only treatment employed was sponging with cold water.

All were discharged on the second or third day after defervescence. Two were laundresses; the others worked out of doors.

TEN SEVERE CASES.

One case entered moribund, death taking place in the bath given shortly after entrance; of this case I can only report that the temperature was 111° in the rectum. In the other nine cases the following symptoms were noted: In all there was profound unconsciousness, with stertorous respiration. In all there was marked rigidity of the whole body and the extremities were extended with difficulty, becoming immediately flexed when not forcibly held. In all the pupils were contracted to a pin-point in size, and did not react to light or other stimulus; the conjunctivæ were deeply injected, and in two cases the eyes were rotated sharply upwards. In eight cases there were general convulsions, frequently recurring. Profuse, involuntary dejections and vomiting were seen in five cases, and noted as absent in two. Albuminuria and casts were found in three cases, and noted as absent in only one instance. In all the cases the pulse was rapid and poor, being several times imperceptible at the wrist. Râles were heard throughout the chest in each case examined. I give the range of temperature with the result in each case:

106°	Death, 7th day, jaundice and pneumonia.
105°	Death in a few hours.
108°	Recovered.
110°	Death, 14th day, edema of pia.
110°	Recovered.
110°	Death in four hours.
111°	Entered moribund.
102°	Recovered (ice-bath at station-house).
109°	Recovered.
109.5°	Recovered.

CASE I. Temperature 106°. Baker. Entered on evening of August 10th. Temperature fell rapidly after ice-water baths, and toward morning he was semi-conscious. During the next few days jaundice developed, and he was delirious. The liver was enlarged. August 16th, consolidation of the lower lobe of the left lung, and death the next day.

CASE II. Temperature 105°. Was put in a cold bath, and removed when the temperature was 101°. He was wrapped in blankets, rubbed vigorously, and stimulated; but he failed to respond. The temperature fell to 93.6°, and he died in a few hours.

CASE III. Temperature 108°. Temperature soon fell under use of ice-cold packs, and in a few hours he was conscious. No untoward symptoms. Eloped on fourth day.

CASE IV. Temperature 110°. Boy of fifteen. Mentally deficient, and a resident of an institution. Profuse vomiting and involuntary dejections. Temperature fell rapidly under ice-cold sponging and packs. He never recovered consciousness. There was marked rigidity of

the neck, trunk and extremities: constant vigilance and occasional twitchings of face and legs. Death on the fourteenth day. Autopsy: Much edema of the pia. When the calvarium was removed the brain looked as if covered with a thick layer of wine jelly.

CASE V. Temperature 110° . Temperature fell quickly to 102° under ice-cold packs and sponging. He was then wrapped in blankets and rubbed vigorously. The temperature fell further to 99° , but rose again to 103° in the evening. There were several severe convulsions. There was moderate fever for several days, but no further untoward symptoms.

CASE VI. 110° . Death in four hours. Convulsions.

CASE VII. 111° . Moribund.

CASE VIII. 102° . Ice bath at the station. Convulsions, otherwise quick and uninterrupted recovery.

CASE IX. Temperature 109° . Was left in cold bath until the temperature reached normal. On removal the temperature continued to fall, reaching 93.6° . During the next two weeks the man was very weak, delirious at times, and the temperature normal or subnormal. On August 26th he was unable to walk alone, and the gait was ataxic; the muscles were flabby, knee-jerks present. Through September he was confined to the bed, but gradually recovered his strength and on October 8th he could walk alone.

CASE X. Temperature 109.5° . Was placed in an ice bath and kept there until the temperature reached 102.5° . After removal the temperature fell lower, to 98.6° . During the evening there were convulsions and a secondary rise of temperature to 107° . He was conscious the next morning; and except for a moderate fever for four days no other symptoms developed.

All of the cases were treated by external application of ice-water, some by full baths and others by pouring cold water over the body as they lay on rubber sheets in bed. In all cases the importance of stopping the application of cold by the time the temperature reached in the rectum 102° was fully emphasized. In those cases that I watched personally I felt that the cold baths were much more efficacious when the superficial circulation was stimulated by the alternate use of vigorous friction and wrapping the patients in woolen blankets for short periods. In addition to the application of cold, the patients were stimulated by the subcutaneous use of brandy and sulphate of strychnia. Sulphate of morphia apparently had a beneficial effect in controlling the convulsions.

The clinical phenomena of severe cases of sunstroke all point to a direct and profound disturbance of the nervous system—coma, contracted pupils, convulsions—all symptoms suggesting some direct effect upon the brain as a whole, rather than discrete focal lesions. In Case IV, the boy, the clinical symptoms strongly suggested some pathological process in the meninges, and the autopsy confirmed the clinical diagnosis, showing that the disturbing factor was an extensive edema of the pia.

Two main theories may be advanced in explanation of the nervous phenomena which follow severe sunstroke; they may be the direct result of pathological changes produced in the brain and meninges, or they may be dependent upon the poisonous action of some toxine set free in the body as the result of the disturbance of the heat equilibrium. I have been unable to find many reports of the post-mortem appearances found after sunstroke, but such as I have found suggest that we may find sufficient cause for the clinical symptoms in the lesions of the brain and meninges.

ONE CASE OF CONTINUED FEVER.

Woman, age twenty-four. Entered my wards August 26th. No items of importance in her family or previous history. On one of the hottest days of the hot period she went in bathing at South Boston Point and stayed four hours in the water. Her head was not protected, and she says she did not wet her hair. Severe headache followed. Five days later a doctor was called who found her temperature 103.8° . She became delirious; had severe headache and backache; pupils regular and small. The pulse was occasionally irregular. The temperature continued, but gradually fell, reaching almost the normal point when she entered the hospital. She entered the hospital, as she was much annoyed by any noise. Typhoid fever was considered, also meningitis, which was suggested by the intense headache and the focal signs in the pupils.

I found the following condition: Herpetic eruption on the lips (rarely if ever seen in typhoid). No enlargement of the spleen. Abdomen negative. Urine negative. She had much headache and seemed weak. After entrance to the hospital there was no fever, and she gradually improved without the occurrence of unfavorable symptoms.

Before she entered the hospital she had symptoms evidently pointing to meningitis, according to the account given me by the doctor who saw her in consultation. I believe that those symptoms were the result of lesions produced by sunstroke.

THE TEACHING OF CLIMATOLOGY IN MEDICAL SCHOOLS.

BY ROBERT DE C. WARD, BOSTON,
Instructor in Climatology in Harvard University.

THE time has come when climatology should be generally taught in our medical schools. It is a subject of great importance to medical men, and one about which they should all have some rational information. In the hope of arousing the interest of the medical profession and perhaps also of provoking further discussion of the subject, the present paper is herewith presented.

The intimate relations existing between atmospheric conditions and health have been the theme of comment and investigation from the days of the earliest writings on medicine and on meteorology down to the present time. From the statement made by Hippocrates over two thousand years ago, that "Whoever wishes to study the healing art properly must do this—first, he must attentively consider the seasons of the year," down to the most recent articles in the last numbers of our medical journals, there will be found abundant proof that medical men have been and are fully alive to the important influences which climatic conditions have on disease. The last few years, especially, have witnessed a remarkable increase of interest in this meteorologic or climatic side of medicine, both on the part of medical men themselves and on the part of meteorologists also. The present activity along these lines seems to be largely, if not wholly, due to the fact that meteorology is itself so young a science that it has not been able, until recently, to offer as its contribution to medical or sanitary climatology anything like systematic and reliable

climatic data from different parts of the world. Medicine, on the other hand, has been so busy with its own new discoveries, that it has not had the time to collect these data for its own use.

The remarkable development during the past few years of our knowledge of the bacterial origin of many diseases, has emphasized more than ever before these close relations between medicine and atmospheric conditions. We now know that the development and preservation of pathogenic bacteria depends to a considerable degree on weather conditions, and we know also that the status of our own bodies, which makes us liable to, or immune from, the attacks of these micro-organisms, depends likewise largely on these same conditions. We know that it is not altogether chance which determines the prevalence of one disease in winter and another in summer; which limits some diseases to one zone and some to another; which induces more or less severe outbreaks according to the character of the season.

It has been too much the custom among physicians—and no one seems more willing to acknowledge this than themselves—to send patients away from home to a different climate in the hope that the change might prove beneficial, when they themselves knew but little concerning the new climate except perhaps that, as a whole, it was drier or warmer than the old one. It certainly cannot be said with justice that such physicians have been to blame in the past when, acting on the best information obtainable, they have conscientiously recommended a new climate to a patient, when it may afterwards have proved that this change was the most disastrous thing that could have been suggested. Such mistakes have been inevitable in the past, for physicians had no means of securing the necessary information, and, furthermore, in many cases they really did not know how many meteorological data are necessary in order that a complete understanding of any climate may be had. The knowledge which not a few physicians have regarding the effect of climate on disease does not go much beyond a realization of the influence of a dry or a moist climate on various stages of phthisis. It cannot be too strongly emphasized that climate has important relations to many other diseases, such as cholera, influenza, yellow fever, paludal and nervous diseases, etc. In the case of convalescence from sickness it often becomes necessary to recommend a change of climate, and every climate is not equally beneficial in every case.

There would be no occasion for writing the present paper were there not some suggestions to offer that point to a way out of the present difficulties. The rapid advance of climatology during recent years, an advance made possible by the extension of meteorological observations to places not previously provided with instruments, has put the climatologist in a position to furnish medical men with reliable and more or less complete meteorological data from nearly all parts of the civilized world. A more careful and systematic study of climate in its relation to health and disease is therefore more possible to-day than ever before. The physician needs two things in order that he may know the effect of climate in causing and curing disease. He must be in possession of accurate data as to the various climatic elements of any place. And he must know what physiological effects these different elements have on the human body. The

information needed under the first head the well-equipped climatologist is ready to furnish. There is no longer any reason on this score for delaying the teaching of climatology in our medical schools.

With a view to ascertaining the feeling of the faculties of our medical schools and colleges on this matter, and also in order to see just how much climatological instruction is now being given in these institutions, the writer sent out, on November 16th last, a circular letter, addressed to the deans or secretaries of a considerable number of our leading institutions of this class all over the United States. In this letter the following questions were asked:

A. What instruction, if any, in meteorology and climatology is now being given in the institution under your charge? (In answer to this question I should be glad to have information as to the number of hours occupied in such instruction; the year of the medical course in which it is given; a general outline of the course or courses, and the name of the instructor.)

B. If no such instruction is now being given, do you consider such course or courses desirable and practicable in your institution?

C. In what portion of the medical course should this instruction come? And how many hours a week, or a term, should be given to it?

D. If considered impracticable to have such instruction given as a part of the regular medical course, would it be advisable to have it given during the regular college, or later school years?

The results accomplished by this letter have been most satisfactory, and the writer is much indebted to the gentlemen who have so cordially answered his inquiries and have shown such interest in the scheme. As was confidently expected, the general sentiment of the majority of those from whom replies were received is decidedly in sympathy with the suggestion that climatology should be taught in our medical schools, and, as was also anticipated, there is a considerable feeling against adding any additional burdens in the way of new studies to the already overburdened medical course. As regards the present teaching of meteorology and climatology in these institutions, very little is done in the great majority of cases. A few lectures on these subjects are given in some of the schools, in connection with the work in hygiene, therapeutics, practice or bacteriology, but, with very rare exceptions, no special course in climatology seems to be provided.

We come now to the question, What should the instruction in climatology provided for our medical students include? The first answer naturally is, As much of the subject as possible. It would be well if every medical man could spare the time to master some such book as Davis's "Elementary Meteorology" (Ginn & Co., Boston, 1894), at once the most concise and the most scientific of the newer text-books of meteorology, and, if he could add to that a general knowledge of Hann's "Klimatologie" (Stuttgart, 1883), a veritable store-house of information on climatic matters. It is certainly not to be expected that any such extended course as is embraced by these two books will be introduced into our medical schools at present. In view of the great diversities in the arrangement of the medical courses in our different schools, and of the greater or less opportunities of introducing a course in climatology into the medical curriculum, it is not thought possible or even necessary, to present here anything like a definite outline of such a course.

The writer ventures, however, to suggest a very brief summary of what he believes a general course in climatology might well include in order to be most useful to medical men.

The main object in the work should be to teach the student what climate really is — how many factors are concerned in it; what its controlling influences are; why, for example, the winter climate of the southern coast of California is so unlike that of the southeastern Atlantic-coast States, or why Cape Town has different climatic conditions from those of Montevideo; what data must be at hand if an accurate knowledge of any climate is to be had. The common impression among all classes is that climate is a simple thing; that if the mean annual temperature and rainfall are known, and a little something as to the humidity, that is all that is necessary. Nothing could be further from the truth than this.

Climatology proper cannot be understood without an elementary knowledge of meteorology. The general facts as to the composition of the atmosphere and its physical properties should be made the starting-point; and in order that a proper appreciation of the value and meaning of climatic data may be gained, every one should become familiar with the construction and use of the ordinary meteorological instruments. These include the wet and dry bulb and maximum and minimum thermometers; the aneroid and mercurial barometers; the self-recording barometer or barograph, the rain gauge, the anemometer, the sunshine recorder, etc. Actual use of these instruments, the determination of the dew-point, relative and absolute humidity, the reduction of the barometer readings to sea-level, the determination of mean temperatures, pressures, and similar reductions, will be found to give a training in practical meteorological work that will prove of great value. This "laboratory work" is of great importance and should not be omitted.

The broad facts as to temperature, pressure and wind distribution over the earth's surface can be learned from the isothermal and isobaric charts in the text-book, and a study of these should precede any more detailed work that may be done later on special climates. In a short course, adapted to the use of medical students, no careful study of the general circulation of the atmosphere need be attempted, but the control of the general wind system of the globe over rainfall, with the important climatic results thus brought about, need special emphasis. Owing to the importance of atmospheric humidity from a medical standpoint, more attention might well be given to that subject than to most others, but perhaps the most important part of the whole study concerns the control of our weather by cyclones and anti-cyclones. A careful study of the daily weather maps, from day to day, supplemented by the text-book, will very soon impress upon the mind of the student the chief facts in our ordinary weather changes. Without such knowledge our weather and its changes from hot to cold, and wet to dry, mean nothing. With this understanding, we are far better fitted to appreciate the climates of other places.

For this preliminary work, thus very briefly outlined, perhaps ten lectures would suffice. The laboratory work with the instruments and on the weather maps, should run parallel with the lectures. The best text-book, as already stated, is that of Professor Davis, and the "Instructions to Volunteer Observers," issued by

the United States Weather Bureau (obtainable on application to the Chief of the Weather Bureau, Washington, D. C.), will be found useful in the instrumental work. It would, of course, be very desirable to have every medical student complete a full course in elementary meteorology, together with laboratory work, before going on to the further study of climatology, but that is hardly possible owing to the time which such a course would occupy.¹

After some preliminary training in meteorology, there should follow a course in climatology proper, of which the following may serve as a rough outline: The astronomical relations of earth and sun; the changes of the seasons; the control of our temperatures by the sun; climatic factors (temperature, humidity, rainfall, cloudiness, wind pressure, composition of the atmosphere), and the data which should be given for each factor — as, for example, in the case of temperature: (a) mean annual, (b) mean monthly, (c) mean annual range, (d) mean monthly range, (e) mean diurnal range for the several months, (f) absolute and mean annual extremes, (g) absolute and mean monthly extremes, (h) mean diurnal variability, (i) average dates of first and last frost, (j) average number of days' without frost, etc.; controls of climate (latitude, altitude, distribution and influence of land and water, ocean currents, proximity of mountain ranges, rainfall, prevailing winds, soil, vegetation); the climatic zones and their general characteristics; the physiological effects of temperature, humidity, pressure; the distribution of disease geographically and climatically; acclimatization.²

In this part of the work the most useful reference books are Hann's "Klimatologie," a new edition of which is promised shortly, and van Bebbber's "Hygienische Meteorologie" (Stuttgart, 1895), a short and concise volume specially adapted to the use of medical men. Hann's work is divided into two parts, of which the first treats chiefly of the controls of climate and the climatic elements, and the second concerns the climates of the different parts of the world. Van Bebbber's book considers the composition of the atmosphere and the climatic elements in their physiological aspects, and discusses the relations of the climatic zones to health and disease. Hirsch's well-known "Historical and General Pathology" will be found useful in treating of the geographical and climatic distribution of disease. With the assistance of the books already mentioned, any teacher may prepare a general course in climatology. In them will be found the essentials, and the course may be made longer or shorter as occasion requires.

A medical man ought to know how to interpret climatic tables. He should understand thoroughly what data he needs, and he should be able to supply any missing data from his own observations, if necessary. There are many facts in regard to a new climate that should be known before delicate patients are sent there for their health. It is not enough to know the mean annual rainfall. This should be supplemented by data as to the monthly rainfalls; the probability of rainy days in every month; the kind of precipitation (whether general rains, lasting for some

¹ In Harvard University the course in elementary meteorology (Geology I) is a half course, and includes about forty lectures, besides laboratory work occupying one to three hours a week for about fifteen weeks.

² In Harvard University the course in general climatology (Geology 19) is a half-course, and includes three lectures a week for about fifteen weeks.

hours at a time, or thunderstorms, giving a heavy precipitation in an hour). A very useful addition is separate rainfall records for night and day, so that it may be known whether the patient will be able to be out during the day and enjoy the sunshine, or whether the general occurrence of the rain by day will keep him indoors most of the time. This point has been brought out by a recent writer in the *Lancet*. So, also, it is well to be informed regarding the prevalence of fog, and regarding its character, whether it is a sea fog, or a land fog; whether it is a general one, or is found only in the valley bottoms at night. Important temperature data, not generally considered by medical men, are the absolute extremes of heat and cold likely to be met with, and the average change of temperature from day to day (mean diurnal variability). The diurnal distribution of cloudiness is an important factor. Whether the cloudiness is greater in the morning, afternoon or night may be of great consequence in some cases, for if the morning and early afternoon are most cloudy and the night clear, some delicate patients might be obliged to stay indoors all day, and might not be benefited at all by the change in climate.

Such instances might be multiplied almost indefinitely. It may be asked at once, Are such complete climatic data available for most places? They certainly are not yet; but the remedy for this state of things lies in the hands of the physicians, for as soon as there is a general demand for additional data, such data will be forthcoming. Our Weather Bureau has always shown itself willing to meet the demands of the people in every possible way. Its recent active interest in the sanitary aspect of climatology is the best possible proof of this. As far as the United States is concerned, our Weather Bureau can be relied upon to furnish physicians with all information of which it is itself possessed, and to take steps to acquire any desired information which it has not.

It can hardly be expected that a brief course, such as is possible in our medical schools, will fully equip the student in climatology. At best it can only partially equip him. But it can at least give him access to the literature that may help him should occasion require; and this, if it accomplishes nothing else, is sufficient warrant for giving such a course. At present comparatively few medical men know where to go for such information. Some of the most important books have already been mentioned. In addition, the following will be found useful:

"Meteorology, Practical and Applied," by J. W. Moore. London: Rebman, 1894. 8vo, pp. 445. A readable book, written by a physician, and containing chapters on "Acute Infective Diseases" and on "The Seasonal Prevalence of Pneumonic Fever."

"Elementary Meteorology," by R. H. Scott. International Scientific Series, 1889. 8vo, pp. 410. This is one of the standard text-books.

"American Weather," by A. W. Greely. New York: Dodd, Mead & Co. No date. 8vo, pp. 286. This volume deals chiefly, as its name implies, with American meteorology, and is especially useful if general climatic information is sought concerning the United States.

"Die Klimate der Erde," by A. Woeikof. Jena: Costenoble, 1887. 8vo, pp. 396, 422. This is in two parts, the first treating of general climatology, and the second of the special climates.

More or less information as to climate is, of course, to be found in the books on hygiene, and medical men do not need to be reminded that in the "Index Medicus" will be found many references to articles on various subjects connected with medical climatology. Most of these articles are on the relation of special climates to special diseases, or concern the physiological effects of some one element, such, for example, as diminished pressure, and do not treat of the general aspect of the study.

A very complete bibliography on acclimatization will be found at the end of the admirable paper under that title, by Prof. Wm. Z. Ripley, in *Appleton's Popular Science Monthly* for March and April, 1896.

In seeking definite information as to the climate of any part of our own country, or any other, it is always best to write to the chief office of the Weather Service for the desired data, rather than to trust chance reports on local climates, unless such reports are issued by physicians or associations of recognized standing. So many circulars containing climatic statistics have been published for advertising purposes that great care is necessary in making a proper selection.

As already stated, it is impossible to lay out any definite course which might answer for every institution. There seems to be a pretty decided majority of the deans of our medical schools in favor of having some instruction in climatology given in their institutions. As to how such instruction should be given, is the question; whether as a part of the regular course, or as a voluntary subject. In the opinion of the writer it would be best at the outset, in most cases, to have the course a short one, at which attendance would be voluntary. Then, if the students showed a disposition to take the course it might easily be extended. He believes further that the subject is of sufficient importance to stand by itself, independent of any other. It would certainly be well for any instructor who wished to do so to speak of the effects of climate in any lectures on hygiene, or therapeutics, or bacteriology. Each man would probably wish to treat the subject differently from any other instructor, because he would see it especially in its relations to his own branch of medicine. But the broad general facts as to climate, which can be and ought to be taught independently of their bearing on any special diseases, should be considered in a separate course. Whether that course shall come in the first, or second, or third, or fourth year; whether it shall be voluntary or required; whether long or short, must be settled in each institution for itself. That the subject is one of prime importance in the education of a medical man none will deny. And that it should be generally taught in our medical schools is acknowledged on all sides.

SMOKING AT MEDICAL MEETINGS. — The Physiological Society of London, we learn from the *British Medical Journal*, has been the only learned society in that city which has allowed its members to smoke at its meetings. The Council of the Harveian Society has lately proposed that smoking be permitted at the meetings, except those at which the presence of patients is required. The object is apparently to increase the attendance at the meetings. Whether the society will approve the proposal or not remains to be seen.

LUMBAR PUNCTURE.¹

BY A. H. WENTWORTH, M.D.

I HAVE been asked by the chairman to make a few remarks on lumbar puncture. I shall allude briefly to some of the difficulties of the operation, and also emphasize the importance of a systematic and careful examination of the fluid. In a certain number of cases in which lumbar puncture is performed one fails to obtain any fluid. In some cases this may be explained by the fact that the point of the needle is not in the spinal canal; or that after several minutes spent in endeavoring to find the canal with the point of the needle, the lumen of the latter becomes occluded by a blood-clot; or that one of the nerves of the cauda equinae may act as a valve across the opening in the needle; or most important of all, the point of the needle may be in the spinal canal but lying between the dura and the bone and not in the subarachnoid space.

The first of these difficulties is overcome by noting the depth to which the needle has penetrated; the direction which it has taken and whether the point of the needle is free, or fixed. By passing a sterile wire through the needle, *in situ*, a blood-clot can be forced out, if the wire is large enough to almost fill the opening in the needle. By withdrawing the needle for a short distance the third difficulty should be overcome. In several cases, I have convinced myself that the needle was in the spinal canal and that there was no blood-clot obstructing its lumen, but from the depth to which the needle had penetrated and the direction which it had taken I suspected that it was outside of the dura on the left side. After withdrawing the needle a short distance and thrusting again, with the point directed toward the median line, the fluid has flowed freely. In one case, punctured, at the time of autopsy, there appeared to be no fluid in the spinal canal. This was not a case of meningitis.

The pain of the operation is solely that of puncturing the skin. This has been ascertained by observing infants and children during the operation and by questioning the latter as to the degree of pain.

The importance of arranging the patient properly should not be overlooked. The patient should lie on the side, with the uppermost shoulder depressed, so that the spinal column presents directly toward the operator. In this way the operator can control the direction taken by the needle because he thrusts directly forwards. The knees should be drawn up to obtain as much convexity of the back as possible in order to separate the spinous processes.

The examination of the fluid should be as carefully performed as in any bacteriological examination. The microscopic examination of cover-glass preparations of the sediment, previously fixed and stained, should never be neglected and the character of the exudation should be noted.

Cultures should always be made from the fluid on blood serum as soon as possible after its withdrawal, and, when possible, a guinea-pig should be inoculated with some of the fluid. Tubercle bacilli are rarely numerous in the spinal fluid from cases of tubercular meningitis and their recognition is oftentimes difficult. The inoculation of guinea-pigs is the surest means of determining if tubercular meningitis is recovered

from. A recent case in which I performed the operation illustrates this: one typical, and two or three doubtful tubercle bacilli were found. A guinea-pig was inoculated, and after thirty-nine days, was killed, and not a sign of tuberculosis could be found.

Inoculations should be made as soon as possible after withdrawing the fluid. If fibrin has already formed it is well to break it up with a sterile wire at the time of inoculation, because the tubercle bacilli are retained in its meshes.

In making cultures from the fluid it is not safe to depend upon the quantity of fluid which can be obtained in the loop of a platinum wire. In several cases I have failed to obtain a growth of pathogenic bacteria because enough fluid was not used. It is best therefore to withdraw one to two cubic centimetres of fluid from the test-tube by means of a sterilized hypodermic syringe and to squirt the fluid over the culture medium. In order to carry out so thorough an examination, it is, of course, essential that every precaution should be used to prevent contamination of the fluid. The patient's back and the operator's hands must be thoroughly cleaned and the needle sterilized. One or more sterile test-tubes, plugged with cotton, are essential. These tubes should be sterilized by dry heat to 150° C. This may be done rapidly by passing the test-tube back and forth through the flame of an alcohol lamp or Bunsen burner until the cotton in the inside of the tube turns brown.

Microscopic examination of the sediment is essential because cloudiness may be caused by dust; by cotton fibres and the dust adhering to them, and by the products of bacteria in cases of septicemia. One or two drops of blood in the fluid will also cause a diffuse cloudiness.

The cloudiness in meningitis, which is caused by cellular exudation, is diffuse and very finely divided. A clear fluid containing small white particles should not be mistaken for it.

Finally, the diagnosis of meningitis at autopsy should never depend upon a macroscopic examination. A case recently autopsied showed no evidence of exudation in the meninges macroscopically. The cerebrospinal fluid, withdrawn during life, contained a great many polynuclear leucocytes. The microscopic examination of the brain and cord showed a well-marked and extensive encephalitis and myelitis and beginning meningitis.

REMARKS ON WIDAL'S "CLUMP REACTION" IN TYPHOID FEVER.¹

BY R. C. CABOT, M.D.

THE credit of the reaction is originally due to Pfeiffer, of Berlin, but this particular application to the diagnosis of typhoid was made by Widal, of Paris, in July of this year. The reaction is for diagnostic purposes. It consists in this: if to a bouillon culture of typhoid bacilli be added the blood serum of a typhoid patient in the proportion of one part of serum to ten parts of the bouillon, a certain reaction takes place which I am to demonstrate to you, namely, an aggregation of the bacilli into groups with a gradual loss of motility, the loss of motility being subsequent to the aggregation into groups and

¹ Read before the Clinical Section of the Suffolk District Medical Society, November 18, 1896.

² In explanation of a demonstration before the Clinical Section of the Suffolk District Medical Society, November 18, 1896.

not its cause. Such a clumping of the bacilli appears a very simple physical process, and it seems as if many other diseases and conditions might produce the same thing. In the last three months I have been attempting to test this and I have tried it in 160 cases, 71 being typhoid and the remainder various other diseases. I have never found anything like a clump-reaction in any disease but typhoid. In 70 out of the 71 typhoid cases I got the typical reaction.

As to the exact way of making this test, I have here a twenty-four hour culture of typhoid bacilli which were originally cultivated from the spleen of a case of typhoid, and subjected to all the tests for the identification of Eberth's bacillus. This culture should be fresh; if over twenty-four hours old the reaction does not always work.² Of that culture I take ten drops with a sterilized medicine-dropper and put them into one of these three-inch test-tubes; then to that bouillon culture I add one drop of serum from the blood of a typhoid patient. The serum is obtained by taking about twenty drops of blood from the ear or finger of a typhoid patient in the ordinary way. Sterilization of the skin is unnecessary because the whole process is done in fifteen to thirty minutes, affording no opportunity for other bacteria to grow. Milk out about twenty drops of blood into a small test-tube, and let it run down the side. The first time I tried this reaction I was disappointed because I could not get the serum to separate. Instead of rising to the top as serum always had done in my previous experience, the serum staid at the bottom, owing to the fact that the edges of the clot stuck to the glass so that the serum was pinned down under the clot. I now separate the edges of the clot from the side of the tube at once with a sharp stick or any pointed instrument so that the serum at once works up. In that way you can get the serum immediately. A drop of this serum is then added to the bouillon culture (ten drops). If the serum is from any disease other than typhoid, no effect is produced upon the bacilli within half an hour. In some cases they seem to be rather more motile than before the serum was added; they do not tend to agglutinate or cling to each other; But if you are dealing with a case of typhoid fever, the bacilli are agglutinated in the way I shall demonstrate. This reaction is not as far as I can ascertain applicable in the early diagnosis of typhoid fever. It is of value in the late diagnosis, and sometimes lasts for weeks after the normal temperature has been reached; it has been reported as long as six months after the cessation of the disease. In the differential diagnosis of such affections as septicemia, meningitis, tuberculosis, pneumonia, the reaction seems to be very helpful.

The reaction can be obtained from the milk of nursing women who happen to be affected with typhoid fever, and occasionally from the urine, but is not reliable because the urine from some normal persons gives the same reaction. The reaction seems to be remarkably simple. It is very easy to see and in marked cases it becomes visible to the naked eye; the clumps become so large that they fall to the bottom leaving the upper portion of the tube clear. The reaction takes place more promptly and effectually in virulent cultures recently obtained from the autopsy. Dr. Wright gave me this morning a culture from the case

of typhoid fever autopsied yesterday and the reaction was remarkably prompt.

I have under this microscope a drop of bouillon culture of typhoid fever to which has been added serum from a case of tuberculosis simulating typhoid fever so closely that the diagnosis was for a time in doubt. On the other side I have the serum of a case of typhoid fever mixed with bouillon culture in the same way. In the first you see the bacilli discrete, in the second they are in clumps. This reaction can also be performed in the majority of cases with the dried blood. I have tried this in thirty cases and it has failed in four. A few drops of blood are dried on a piece of paper, the paper cut out round the drops and the dried blood soaked in a bouillon culture of typhoid bacilli at the bottom of a test-tube. Johnson's experience³ seems to indicate that the whole blood, dry or fresh, has more clumping power than the serum alone.

Clinical Department.

THE CAUSE OF BOWING OF THE LEFT FORE-ARM IN RACHITIC CHILDREN.¹

BY J. S. STONE, M.D., BOSTON.

THE two cases which I briefly report are of interest solely from an etiological standpoint.

CASE I. L. F., aged fourteen months, of Jewish parentage, was brought to the out-patient clinic at the West End Nursery on July 8, 1896. She was breast-fed, but also had always been given whatever she

CASE I.

CASE II.

wanted to eat, including tea, coffee, cake and candy. She had never had any illness, except a cold during the preceding winter. She was in fair general condition, though presenting well-marked evidences of rickets of a moderate grade. The radial epiphyses were considerably enlarged. The anterior fontanelle admitted a finger. There was no marked rosary or bowing of the legs.

¹ Read, by invitation, before the Warren Club, November 3, 1896.

² New York Medical Journal, January 16th.

³ Widal (Presse Médicale, October 4, 1896), has lately obtained the reaction with old cultures, and even with dead bacilli.

The left forearm presented at the junction of the upper and middle thirds of the shafts of both the radius and ulna, an angular backward bowing of about forty degrees, a little greater in the radius than in the ulna. The motions of the elbow were normal, excepting that the deformity slightly increased pronation and limited supination. The right forearm was normal.

The mother associated the deformity with a fall from a chair four months previously. This gave rise to no symptoms, however, for several days, when the deformity was observed. At that time the child was just beginning to walk. Careful inquiry showed the great improbability of green-stick fracture, which the deformity at once suggested.

CASE II. M. E. C., aged two and one-half years, of Irish parentage, was brought to the out-patient clinic at the Children's Hospital, in the service of Dr. Lovett, through whose courtesy I report the case. As a baby she had been healthy, and was breast-fed. At nine months she had diarrheal troubles, followed by whooping-cough. For a year she had been rachitic. She had a square head with a closed fontanelle. There was marked retraction of the sides of the chest, a considerable rosary, a prominent abdomen and slightly enlarged spleen. The radial and tibial epiphyses were markedly enlarged. There was slight anterior and outward bowing of both tibiae at the junction of the middle and lower thirds of the shaft. The curves of both clavicles were exaggerated. There was the long rachitic curve of the spine. The left radius and ulna were bowed backwards, the deformity causing a sharp angle of about forty degrees just above the middle of the shafts of the bones. There was no limitation of motion. The right radius and ulna were normal. The deformity was first noticed as the child was beginning to walk. There was no history of any injury whatever.

The accompanying photographs show the nature and cause of the deformity. Each mother was right-handed, and in helping her child to walk, grasped its left hand and wrist. The bones of the forearm bent exactly where her little finger pressed against them.

Medical Progress.

REPORT ON NEUROLOGY.

BY PHILIP COOMBS KNAPP, A.M., M.D.

(Concluded from No. 4, p. 90.)

SEROUS MENINGITIS.

QUINCKE has reported⁷ ten additional cases in confirmation of his former views upon this affection. Among the causes of the affection he reckons injury to the head, persistent mental over-exertion, acute and chronic alcoholism, acute febrile diseases and pregnancy, otitis media, influenza, and exposure to wet and cold. In two cases the large size of the head led him to suspect that a certain amount of internal hydrocephalus had been present from childhood. In three of his cases the trouble was chronic from the start, of gradual onset, and subject to exacerbations; in four others the onset was acute. The symptoms are indicative of increased intracranial pressure. In some cases there is moderate fever, at least in the initial

stages, but in others there is no rise of temperature at all. Headache is a constant symptom, and vomiting and vertigo are very common. There are often loss of memory, mental hebetude and stuporous conditions, with apoplecticiform seizures and periods of unconsciousness. The cases of sudden onset may begin with an apoplectic seizure or loss of consciousness. Motor inco-ordination, weakness and even paralysis may supervene. Involvement of the motor cranial nerves is occasionally met with, and changes in the optic nerve in the nature of swelling, hyperemia, venous enlargement and optic neuritis of a low grade are common. These changes may lead to complete blindness. The pulse is often slow. In the majority of his cases Quincke performed lumbar puncture, finding a marked increase of the intraspinal pressure, and a clear or slightly turbid fluid, of a low specific gravity, containing some albumin but no tubercle bacilli. This procedure often gave very marked relief. In one case of purulent otitis, with pain and tenderness in the head, mental hebetude, uncertain gait, nausea, irregular pulse, fever, mild optic neuritis and hemiparesis, an abscess was suspected and trephining was performed, but no abscess was found. The autopsy showed a considerable degree of intracranial pressure, with flattening of the convolutions; the brain was moist and filled with punctate hemorrhages, and there was much thrombosis of the veins with a region of softening in the right lower lobe. Two months before, the patient had had an attack of headache, nausea and faintness, with some slighter changes in the optic nerve, which had been relieved by mercury. This was thought to be a serious effusion, which by pressure led to venous thrombosis starting in the choroid plexus. Some of the cases, especially in anemic young women, begin suddenly, without fever, run an acute course, and often terminate favorably. Here it seems doubtful whether the meningeal effusion, which has been demonstrated by lumbar puncture, is really of an inflammatory nature, and Quincke suggests that it may be due to an exudation such as often occurs in other parts of the body, an angioneurotic hydrocephalus. In other cases the trouble may become chronic or after a protracted duration, recover, leaving behind some permanent disability, as blindness from the optic neuritis. Even the chronic cases, however, may eventually recover, after ten months in one case, but here blindness and other disabilities may be left. Recurrences are common. Two of the ten cases terminated fatally. The diagnosis is still difficult, the trouble being most often confused with tumor and purulent meningitis. The optic neuritis is less marked than in tumor, and the fever and spinal rigidity less than in purulent meningitis. Lumbar puncture may aid in excluding the latter. The cases do best under mercury, and lumbar puncture often gives temporary if not permanent relief.

TETANY.

Sarbó⁸ has sought in vain for a single cause for tetany. Frankl. Hochwart considered it to be of infectious nature on account of its epidemic-endemic occurrence, its development with febrile symptoms, its occurrence in the prodromal stage and in the course of typical infectious diseases, the occurrence of hallucinatory confusion in its course, its co-existence in several members of the same family or household, and the fact that in some years very many, and in other years

⁷ Deutsche Zeitschrift für Nervenheilkunde, ix, 149, 1896.

⁸ Deutsche Zeitschrift für Nervenheilkunde, viii, 242, 1896.

very few cases were seen. The infectious nature of the trouble, however, has not yet been proven bacteriologically or experimentally. Its occurrence after the removal of goitre, in rickets and pregnancy, etc., indicates that there is no specific micro-organism which causes the disease, since it is hard to believe that other causes beside the specific agent, if there were such an agent, would produce it. It is more probable that it is dependent upon a general disturbance of nutrition. It is well known that tetany may develop in the course of various infectious diseases, typhoid, scarlet fever, diphtheria, malaria, etc., after poisoning by various substances, ergotine, alcohol, chloroform, etc., and after the intoxication from thyroidectomy. It may also develop in cases of gastric dilatation, perhaps as a result of toxins absorbed in this condition. Sarbó in a study of the changes in ganglion cells after phosphorus and morphine poisoning, found that the changes were the same with each poison, and concluded that the poison produced a general disturbance of nutrition which resulted in disease of the ganglion cell. Schaffer found the same changes in the ganglion cells after poisoning from lead, arsenic and antimony, and Pandi after poisoning from cocaine and antipyrine. These changes were most pronounced in the ganglion cells of the anterior horns of the spinal cord. In other affections with marked changes in nutrition, notably rickets, and also pregnancy and lactation, tetany is very common. There is, finally, a group of cases in which no poison can be detected, but which are characterized by an epidemic occurrence. In these epidemics it has been found that cobblers and tailors have been most frequently attacked, which speaks against a specific infection. Oppenheim thought that in the case of cobblers there might be some poison in the leather. Sarbó concludes that in many cases the cause of tetany is a general disturbance of nutrition, excited either by different poisons, or by physical conditions, or by disease affecting the whole organism. In regard to the seat of the disturbance in tetany, Sarbó refers to Herbert Spencer's molecular theory of nervous action, and shows that the nerve fibre acts chiefly as a conductor of motion, while the ganglion cell acts in strengthening such motions by exciting greater molecular changes. The excitation of pronounced muscular movements after slight irritation, such as is seen in tetany, indicates that the disturbance is in the cells rather than in the fibres. We have an increase of the normal muscular tonus, which is regulated by the cells of the anterior horns, and is lost in destructive disease of these cells. Moreover, the poisons which cause tetany also give rise to changes in these cells. Weiss found such changes in some cases of tetany. This theory of a central origin of tetany is confirmed by the bilateral character of the symptoms, by the fact that the spasm may arise from reflex irritation, pressure on a nerve-trunk causing contraction on the opposite side, and the existence of ankle clonus. Vasomotor symptoms hint at an implication of the medulla, and hallucinatory confusion and disturbances of consciousness point to an involvement of the brain. The cramps, Chvostek's phenomenon, and the mechanical and electrical hyperexcitability point to an involvement of the motor cells in the cord, but the sensory hyperexcitability, the paresthesiæ and the trophic disturbances indicate that the sensory and trophic cells are also affected, and the psychical symptoms show that the cortical cells are also involved. Tetany, there-

fore, is to be regarded as a disease of the cells of the central nervous system.

RAYNAUD'S DISEASE.

Calmann⁹ discusses the question as to whether Raynaud's disease, symmetrical gangrene of the extremities, is always to be referred to some organic lesion of the nervous system, or whether it may not occur as a purely functional disease. The reported autopsies have shown structural disease of the nervous system, notably neuritis, and Bervoets has shown by experimentation on animals that section of the sciatics gives rise to changes in the arteries, thickening of the arterial walls with contraction of the lumen, atrophy of the muscular layer, and the formation of aneurisms. Later symmetrical gangrene developed, which Bervoets thought due to the vascular changes. Calmann reports two cases. In the first there was paralysis of the legs with atrophy, loss of sensibility, absence of knee-jerk and paralysis of the sphincters. Three months before death there developed paroxysms of edema of the legs, gangrene on the backs of the feet and erythromelalgia. The autopsy showed a sarcoma involving the third and fourth lumbar roots. A second case showed symptoms of a tumor compressing the cauda equina, with edema, pallor and lividity, at first paroxysmal, but later stationary. In spite of these cases and the reported autopsies, Calmann claims that we cannot set aside the cases which present the symptoms of Raynaud's disease, where the most exhaustive methods of clinical research fail to give any evidence of any organic nervous disease. He cites four other cases where, in addition to the usual symptoms of Raynaud's disease, the patients suffered from many extremely painful felons, especially on the hands. Symptoms of syringomyelia and leprosy were wanting. He concludes that the changes caused by Raynaud's disease furnish especially favorable conditions for the development of pyogenic organisms and the production of felons. In three cases changes were found in many parts of the skin corresponding to those of scleroderma. He considers the two affections to be due to a single cause, which in many cases is a functional affection of the nervous system. When Raynaud's disease occurs as a symptom of organic disease of the cord, it seems to be less intense.

In support of this opinion it is to be remembered that Lévi,¹⁰ on the basis of two cases of his own and a careful study of other reported cases, has maintained that there is a form of Raynaud's disease and erythromelalgia which may be purely hysterical, arising from some lively emotional disturbance, which may begin quite acutely, and may even go on to gangrene. Minor¹¹ has also reported a case in a telegraph operator, nervous and debilitated, who was at work at the telegraph key during a severe thunder shower. She had always feared a shock under such circumstances, and after a severe thunder-clap she became much frightened. She developed a typical hysteria, and swelling, cyanosis, and finally gangrene of the fingers of the right hand, with a weaker pulsation of the arteries in the right hand. Fuchs¹² has also reported a case of Raynaud's disease with felons and scleroderma, and holds with Calmann that the two affections are due to the same cause.

Camillo¹³ reports the case of a child a year old, who, after a four days' fever with convulsions, possibly influenza, had a macular bluish-red eruption which disappeared in twenty-four hours. This was followed by the appearance of violet spots on various parts of body which soon became black, and on the hands and feet developed into large bullæ with sanguinolent contents. These were not perfectly symmetrical. Later a typical gangrene developed. The vessels in the gangrenous parts removed were enormously dilated, with intact walls and complete thrombosis. Slight and presumably secondary changes were found in the nerves. The gangrene was attributed to thrombosis, which, in its turn, was due to a slowing of the circulation, from disturbances of the vasomotor innervation. He considers that all the theories of Raynaud's disease which assume an organic change in the blood-vessels or the nervous system are inadequate, and that a functional disturbance of the spinal vasomotor centres is the basis of the trouble. This functional disturbance causes vascular spasm, and this in turn thrombosis and gangrene. Neuritic and arteritic processes serve only as predisposing factors. Raynaud's disease forms a group which includes the cases where these processes occur, and also the cases of symmetrical gangrene of diabetes. The trophic centres may also be in a condition of abnormal irritation. We can thus understand why gangrene may occur without previous local asphyxia or syncope. The central disturbance of function is sometimes autochthonous, but more frequently it depends upon abnormal sensory irritations coming from the extremities to the vasomotor and trophic centres which are also abnormally irritable, so that these irritations, which would not act on normal centres, set free abnormal reflex disturbances. In these mild cases he has carefully tested the vascular reflexes, finding no increase, but a remarkable instability of the vascular tonus, such as does not occur in health.

Reports of Societies.

CLINICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

E. W. TAYLOR, M.D., SECRETARY.

REGULAR Meeting, November 18, 1896, the President, DR. W. F. WHITNEY, in the chair.

DR. HENRY JACKSON read a paper on

INSOLATION.

DR. LOCKE: After listening to the admirable account of certain cases of sunstroke which we have just heard, I hope a short consideration of the powers with which nature has endowed us to withstand the extremes of heat and cold, which a residence in Boston accustoms one to, will not be altogether unwelcome. At the outset it cannot be too clearly borné in mind that the life of a human being can only be continued by means of a continuous generation of heat, while on the one hand life can only persist if this generation of heat does not raise the temperature of the body beyond a certain definite limit, and on the other hand, the loss to the external medium of the heat generated in the body must be so graduated that the temperature

of the body does not fall below a lower limit, a fall below which is as unfavorable to the life of the organism as is a rise of its temperature above the upper limit. The means whereby the regulation of the temperature of the body is carried on, can be easily grouped under two heads: variations of the rate of loss of heat, and variations in the rate of production.

Heat is lost to the body in three ways: First, by heating the liquid and solid excreta; that, of course, takes a very small amount, calculated to be about five per cent. of the whole amount of heat lost by the body. Then heat is lost in warming the air taken into the lungs and expired again, and in saturating, or practically saturating this air with aqueous vapor. This has been fairly reliably calculated to take about 15 per cent. of the whole amount of heat lost by the body. The remainder, some 80 per cent., is lost through the skin, partly, of course, by conduction, and radiation and otherwise, by the evaporation of the perspiration. Then we come to the regulation of the body temperature by variations of the rate of heat production. The evidence for the existence of a mechanism by which this is carried on, is mostly indirect and depends not on measurements of the variations of the amounts of heat produced, but by measurements of the amount of chemical change going on in the body, as shown by changes in the amount of oxygen inspired, used up by the organism, and by changes in the amount of carbonic acid produced, and here we come upon a very interesting contrast established by the work of Pflüger and his pupils between the action of variations of external temperature upon the cold-blooded frog and on the warm-blooded mammal. If the temperature of a frog is raised, the amount of carbonic acid produced by the animal, and the amount of oxygen consumed are increased, that is to say, a greater amount of chemical change takes place in him. If, on the other hand, the temperature is lowered, the opposite effect is produced, that is to say, a frog behaves exactly as would a mixture of reagents in the chemist's retort, heat exercising its action in increasing the amount of chemical change going on, and cold diminishing it. But in the case of the warm-blooded mammal, the opposite effects are produced. Within certain limits a rising temperature lessens the amount of chemical change, lessens the combustion going on; a falling temperature on the other hand increases the amount of combustion. There is obviously, of course, here a purpose. There must exist in the case of the warm-blooded animal some mechanism, whereby a falling external temperature is responded to by an increased combustion in the body tending to counteract its influence, and there can be no doubt that this mechanism is a nervous one. If, for instance, the mammal be curarized, it is found that he responds to external temperature exactly in the same way as does a cold-blooded animal. Curare, of course, cuts off the nervous impulse from the muscles, the voluntary muscles, and we have abundant evidence that it is the muscles especially which generate most of the heat produced by the body. If, then, the connection of the muscles with the central nervous system be severed, this can no longer exercise its regulating influence upon the muscles, and they behave under variations of temperature as do the tissues of the cold-blooded animals, the combustion in them being increased by a rising temperature, and a falling temperature having the reverse effect. In the same way, if instead of

¹³ Rivista clinica, 1896, Ref. in Neur. Centralblatt, September 15, 1896.

cutting off the nervous impulse at the point where the end of the motor nerve comes in contact with the muscle substance, we cut it off higher up by dividing the cervical cord of the mammal, we find he behaves in the same way as does the cold-blooded animal, so that it would seem that the part of the central nervous system which presides over the central mechanism regulating heat production, must be higher than the cervical cord. More than that, it is not with absolute clearness at present established. The existence of various so-called centres in the brain has been claimed, the destruction or stimulation of which produces various changes in heat production and in the body temperature, but although, no doubt, effects on the body temperature and on heat production are produced by lesions of various parts of the brain, yet it cannot be said that the knowledge we possess is so clear and definite as to aid much in understanding the mechanism of heat control in the body.

Aronsohn and Sachs have shown that if a certain small area in the optic thalamus near the median line be injured with a needle, that a rise in the body temperature takes place of 3° or 4° C., which lasts some hours. They have shown this is not an effect due to destruction of nervous tissue, the same effect being produced by careful weak faradic stimulation. Of course this is a suggestive piece of work, but does not help one to understand very clearly the processes actually going on in the body in relation to heat control. The same remark applies to the work of Wood and Ott, in Philadelphia, who have shown that in the dog an increase of heat production accompanies the destruction of parts of the cerebral cortex in the neighborhood of the crucial sulcus.

The information I have hitherto been able to give you is about all I think that is at present clearly known with relation to the mechanism of heat control in the body, and we have now to inquire within what limits, especially in relation to the question of sunstroke upper limit, does this mechanism do its work properly. Rosenthal has in this relation performed some experiments on the rabbit which have considerable interest. He found if he kept a rabbit between the temperatures of 51.8° and 89.6° F., that the rabbit was able to maintain its normal temperature; between 89.6° and 96.8° F., the temperature of the rabbit rose to 105.8° to 107.6° ; but there the animal entered upon a condition of balance and the temperature remained steady, the rabbit being able to continue with this increased body temperature in a fair state of health for several days. The temperature 89.6° to 96.8° is a little higher than the heat of the skin of the rabbit. If the temperature of the external medium was raised to between 96.8° and 104° , speedy death took place, but successful treatment was possible by lowering the temperature of the external medium in time. The engineer, Stapf, who directed the work of the St. Gotthard tunnel, made some interesting observations on his workmen in regard to the influence of increased external temperatures. Many of them were exposed for long periods to the temperature 86° F., in an atmosphere saturated with moisture; and under these conditions they were in a state of continued fever (their temperature being 104° F.), while, nevertheless, enjoying fairly good health. So that up to within a certain upper limit the organism can accommodate itself very fairly to an increased temperature. But what causes especially are those which bring about

the break-down shown so clearly in cases of sunstroke, at any rate, those in which the temperature is considerably raised? First of all comes, of course, that where a man is brought into a medium, the temperature of which is as high or higher than that of his skin, not of his body generally, which of course is higher, the loss of heat from the body by means of conduction and radiation ceases to take place; the man can only cool himself down by the evaporation of his perspiration. That, of course, is an important loss to his powers of heat control. In addition to that, we have to bear in mind that although the organism can by means of the nervous mechanism control the amount of heat production, diminishing, if need be, this heat production to a certain extent, there is a limit beyond which this diminution cannot go; because, of course, further diminution beyond this limit would be followed by cessation of life through too greatly diminished metabolism, and therefore, however warm the external medium, the human body must still continue to add its heat, so to speak, to that of the external medium. In this connection the bad effects of exercise which have been well brought out to-night may be mentioned, because, obviously, if a man is obliged to continue active exercise while exposed to a high external temperature, the lowering of his temperature by means of diminution of heat production is practically impossible. He has to keep on producing heat by means of his muscles thrown into increased activity by the forced exercise, and one important power of keeping his body temperature down is lost to him. Next, one has to take into consideration the exhaustion of the thermotaxic mechanism. This mechanism is nervous, and, like other nervous mechanisms in which at any rate ganglion cells enter, can be exhausted; so that a man exposed to a temperature sufficiently prolonged may, although able for a certain time to maintain himself in it, at last break down completely. And now there is another action of a high external temperature to be referred to, that very severely tells upon the organism exposed to it, and due to the fact that once the power of heat regulation begins to fail, once the temperature of the organism begins to rise, then the muscles, and of course the other tissues of the body as well, but especially the muscles which are the thermogenetic tissues, *par excellence*, act in exactly the same way as do the tissues of the frog I mentioned earlier. In spite of the lessening of the nervous impulses reaching the tissues, due to the thermotaxic mechanism, and tending to lessen their metabolism, they are bound to respond to their rising temperature by an increase of chemical change going on in them. This very response raises again their own temperature, and again they are spurred on to increased activity, so that we have here an avalanche-like and almost suicidal mechanism on the part of the organism, especially dangerous when the power of heat-loss is seriously interfered with. From all that has been said it will be seen then that we are not altogether without an explanation of the phenomena of heat stroke, at any rate of those phenomena which takes place in the form associated with a high rise of the body temperature.

With regard to those forms of heat stroke in which the body temperature is not raised, there has been a theory put forward by Maas, which I think merits a certain amount of consideration. It is that the bad effects in these cases may be essentially due to the loss of fluid to the organism, consequent on the enormously

increased perspiration taking place under increased heat—to an anhydremia, as Maas calls it. Another source, in addition to this, of the various troubles in these cases of sunstroke without increased temperature may exist in the fact that the thermotaxic mechanism, the mechanism controlling heat production, may go too far; it may so depress the activities of the tissues of the organism, especially of the muscles, that they are left in an utterly helpless condition; and thus may be explained those forms of prostration apart from a greatly increased temperature, some of which have been described this evening.

DR. J. H. WRIGHT spoke on the pathological anatomy of sunstroke.

DR. BUCKINGHAM: I think the division into cases of sunstroke proper, and cases of heat exhaustion, made by Dr. Jackson is extremely practical for treatment and for clinical observation. I do not think it has been universally accepted. I should go farther, and say we might make a division of true sunstroke into the cases in which there is a high, tense pulse, and those in which there is a weak pulse. It seems to me that this has not been sufficiently dwelt upon by writers in general; and it is of great importance in the treatment. A case may have a strong, tense pulse; and there is no very great danger of producing collapse in treating it with cold, whereas with a very weak pulse there may be. I have seen a number of cases of heat stroke in which there was no exposure to the sun. At the hospital this year I had one such case in a baker, another in a man working in a stable. In one of the papers I read of a man who had a sunstroke in his room, and died on the way to the hospital.

There is another point I think might well be dwelt upon, and that is the prodromata, which, however, are sometimes entirely absent. They have occurred in quite a number of cases that have come under my observation. For instance, one patient came to the hospital last summer with a sunstroke, and we found afterwards that he had been suffering from severe headache in the sun for two or three days beforehand. A private patient of mine, an inspector of the telephone company, had been exposed during the same time, had been avoiding the heat as far as he could without giving up work; he had headache, and had got to the point where he stopped sweating. He left off work merely because work was over at night, and an hour or two later I found him at his house with a comparatively mild sunstroke. A certain number of these cases recover consciousness without treatment, sometimes permanently and sometimes only temporarily. I saw a gentleman last summer who had been exposed to the sun, going about in the streets; he went to his club, and looked so miserably that the people gave him some brandy. He fell forward on the table. By the time his son got there, he had recovered without treatment sufficiently to get into a carriage. Oftentimes patients will lose consciousness, recover it and lose it again. A man was picked up in the street unconscious and sent in in a police ambulance. When he arrived, he sat up in the chair and gave a more or less connected history of himself to the house-officer, and then shortly became unconscious again. Or, we may have the fever return after it has gone away. One man came into the hospital with a temperature of 108.5°, was treated, his temperature fell to 100° or 101°, and he seemed in pretty good condition, but four days afterwards he had a rise to 110°. His

condition then suggested very serious cerebral disturbance; the question of meningitis was raised, but it was decided not to be meningitis. Looking back, one can say it was not meningitis. He had complete recovery after a few days, but his temperature remained up a little for a week or more. That man has been perfectly well ever since. With reference to post-mortems, I would like to refer to the post-mortem mentioned by Dr. Jackson. If one has not had the opportunity of seeing it, I think he would hardly guess at the amount of edema that took place in the brain. When the top of the skull was removed there was no sign of any convulsion, the appearance was like that of a jelly-fish.

The post-mortem stopped at that point some twenty minutes, during which there was a steady pattering of clear serum upon the floor, after which the brain resembled brain. With reference to treatment, I think it important to observe the distinction between cases of tense pulse and those in which the circulation is very poor. The point is that we do not want to produce collapse by the use of cold, which is the common treatment. In almost all the cases I saw last summer the circulation was exceedingly poor at the time they came under observation. After the first one or two, I gave very particular directions to the house-officers, and they were carried out with great intelligence and fidelity, and the result was we had no more collapse. Although the patient had an ice-cap as soon as he came in, he was not to be put in a bath until the circulation was restored. The first thing to do was to bring up the pulse by brandy, strychnia, etc.; after he began to have a good pulse he was to be put in a bath, but to remain only until the rectal temperature fell to 103°. After that plan was adopted there was no more collapse serious enough to be worth mentioning, which has not always been my experience. The temperature continues to fall after leaving the bath.

DR. G. G. SEARS: As Dr. Jackson has said, a number of these cases were in my service; but he has left very little for me to add in regard to any one of them. The particularly interesting cases to me on account of the difficulty in diagnosis were those of continued fever from heat. During the summer I saw a number of cases whose clinical history was something like this: there was a short prodromal history of twenty-four hours, occasionally accompanied by a chill, and followed by a continued fever rising to 103° or so for a few days or more and then a gradual fall. During the earlier stages there might be a little diarrhea, but by the time they came under observation this had usually ceased. There might also be a little delirium toward night, but nothing which approached a typical typhoid condition. Physical examination was negative except for a possible pimple or two suggesting rose-spots, no enlargement of the spleen could be made out. These cases were very similar to those which Guiteras had observed in Key West and described under the name of thermic fever, but which were locally called typhoid, partly for the lack of a better name and partly because it was more satisfactory to the patient to feel that he was ill with a disease of which he had a definite conception.

For very much the same reason a diagnosis of questionable typhoid was made in many of these cases, and as long as they recovered there was no way of proving its incorrectness. One of them, however, died; an autopsy was made and while a positive diag-

nosis of thermic fever was impossible from the indefiniteness of the history, partly due to the patient's condition and partly to the very limited command of English, it satisfies the conditions more fully than any other. He was an Italian of the laboring class and had been ill nine days before he was admitted to the hospital. On entrance his temperature was 105° and almost immediately shot up to 107.8° . From that it was brought down to normal by cold baths, but again rose and ran along at a fairly high level for two days, when he died. He was delirious and before the end his appearance was somewhat typhoidal. Physical examination was practically negative. A little hypostatic congestion of the lungs was made out and the abdomen was somewhat distended so that the splenic area of dulness was not readily determined. Its edge could not be felt. At the autopsy a little congestion of the brain was found, and there was also some congestion of the lungs, with edema. The spleen was a good deal enlarged. Beyond this there was nothing to be found. Cultures made from various organs were negative.

The report of these cases recalls an incident which occurred when I was house-physician at the Massachusetts General Hospital, and which illustrates how powerful an agent fatigue from overwork is in the causation of heat stroke. Contrary to what I understood Dr. Jackson to say regarding the greater prevalence of such cases during hot and dry weather, the thermometer, if I can trust my memory, was not over 85° or 86° , and the day was cloudy and sticky. The militia were returning from camp and equipped in their heavy uniforms were forced to make a long parade through the streets. They dropped out all along the line of march; and after reaching the Common so many of them collapsed that one of the other house-officers, who happened to be passing and who hurried back anticipating that many of them would be brought to the hospital, reported that it looked like a battle-field. Within half an hour thirteen cases were brought in in all stages of sunstroke—some unconscious, others with convulsions, others with simple muscular spasm. All recovered under treatment.

DR. GREENLEAF: Fortunately cases of heat stroke are not common in Boston, as the summers are relatively cool. Therefore individual experiences may help in the better understanding of the treatment of this condition. I should like to say a few words regarding it. My attention was attracted to the subject when a house-officer at the City Hospital. Such cases were always of interest, as, like opium cases, they responded so satisfactorily to treatment. I recall very vividly the cases from the parade referred to by Dr. Sears. The hospital cases and certain others seen since illustrate the principles of treatment to which I would call attention.

Two general lines are indicated: First, the reduction of temperature; and, secondly, the combating of symptoms, such as prostration, incident to special types of the condition.

Authorities are agreed that the rapid abstraction of heat is of the first importance, but directions for this are often obscure and inadequate. Some refer to antipyretics. Nearly all refer to the use of baths. Regarding antipyretics our experience was negative. At that time antipyrine was freely used in a variety of febrile states. While it was temporarily efficient in

such fevers as typhoid, it did not act equally well in heat stroke. In one case that we noted with especial detail no "drop" resulted till the patient was put in a bath. I should not advise antipyrine or allied drugs, on account of their depressing effects, for depression has to be combated in many cases.

Regarding baths, one must bear in mind the objects to be attained. As I understand it, their good results are due partly to the abstraction of heat and partly (perhaps even of more importance) to their stimulant effect on the nervous centres. It is not enough to simply put a patient in a tub of cold water. Indeed, such a treatment may do harm by producing dangerous congestions of internal organs. To be most efficient the cutaneous circulation should at the same time be kept as active as possible by brisk rubbing. Rubbing may be carried out in a tub, but it is more conveniently done on a bed or table, meantime sprinkling or sponging the patient. The most effective way is to use ice. This cools quickest and stimulates most.

Two cases that I attended on one of the hot days of last summer illustrate the value of this method of treatment. The first was of a baker. He was overcome about four A. M., while at work in the kitchen of one of our large hotels. He presented a typical case of heat stroke of asthenic type. He was unconscious, cyanotic and with a labored pulse and breathing. His temperature was about 106° . He was then stripped, laid on a table and rubbed vigorously with ice and hands alternatively. The ambulance, which had been summoned on first seeing the case, arrived within half an hour. At that time consciousness was returning. His skin was rosy and he was so much improved that on arrival at the hospital he was entered simply as a case of heat prostration. At four P. M., of the same day, I attended a little boy. He had been playing in the hot sun since morning, but a bad headache and general malaise had driven him home. His temperature was 104 , the skin dry and hot. He was perfectly conscious but was in the beginning of an attack of heat stroke. He was treated exactly as in the other case. Within ten minutes the temperature became normal. I put him to bed and in a few minutes more he was sleeping peacefully. Except that he had a headache for a few days he suffered no further inconvenience.

As regards the use of medicinal stimulants, here again more precise directions are needed than are usually given. Alcohol, as advised by some, seems hardly wise as it tends to unduly flush the brain in addition to its stimulant effect on the heart. As much of the danger of heat stroke is due to the engorgement of the cerebral vessels, theoretically, at least, alcohol is contraindicated in most cases. Digitalis and strychnia on the other hand, from their tonic effect respectively on the heart muscles and nerve-regulatory mechanism, are of great value in the cases in which prostration is associated.

The treatment of the possible sequelæ of heat stroke is a distinct subject. I will not say anything about it as it is not properly included in this discussion.

LORD LISTER. — The British medical journals note with satisfaction that Sir Joseph Lister, on his elevation to the peerage will take the title of Lord Lister, and not Lord Kinnear, or Lord anything else.

Recent Literature.

Die Mikrotechnik der Thierischen Morphologie. Eine kritische Darstellung der Mikroskopischen Untersuchungsmethoden. Von STEFAN APATHY. Erste Abtheilung, 8vo, pp. iv, 320. Braunschweig: Har-ald Brühn. 1896.

A Text-Book of Histology, Descriptive and Practical. By ARTHUR CLARKSON. With 174 original colored illustrations, 8vo, pp. xx, 554. Philadelphia: W. B. Saunders. 1896.

Directions for Work in the Histological Laboratory. By G. CARL HUBER. Second edition, 8vo, pp. 176.

Text-Book of Histology, including the Microscopical Technique. By PHILIP STÖHR. Sixth edition. Translated by EMMA L. BILLSTEIN, M.D. Edited, with additions, by DR. ALFRED SCHAPER. With 268 illustrations, 8vo, pp. xvi, 344. Philadelphia: P. Blakiston, Son & Co. 1896.

Of the four books we have to notice, that by Stöhr is the most important and valuable, for we consider it the first really thorough and satisfactory students' manual of histology which has appeared in English.

Apathy's volume is the first part of an exhaustive historical and critical survey of microscopical methods, and may be said to be an almost indispensable companion for the advanced specialist. The extreme diffuseness of the author's style and the ponderous philosophy with which he discusses trifles are defects seriously to be regretted. All that he says could *easily* be said in one-third the space, and the reader cannot but smile to find a large octavo page devoted to a discussion of the size of cover-glasses. None the less the work is valuable for its thoroughness, for its criticisms, and for its clear presentation of the essential principles of technique, especially in the matter of staining, and it ought to go far towards terminating the apparently endless re-invention of devices. It is the only work recording the *progress* of methods, and it is rich in suggestions for further progress. We shall welcome the second part.

Stöhr's Histology in an English translation is sure of a favorable reception. The original work has already a very high reputation, won by its conspicuous merits. It is noted for the clearness, thoroughness and brevity of its descriptions; and so far as the beauty and accuracy of its illustrations are concerned, it has probably no equal among students' text-books. In successive editions the author has incorporated the latest results of research, thus keeping the book always abreast with discovery. The numerous "technical directions" are admirable, and will be found of great value both to beginners and advanced workers. The unique combination of merits in Professor Stöhr's treatise has secured for the German editions a sale, which has already amounted to many thousands. In brief, the reputation of the original work is so high and well established, that it is unnecessary to do more than add a few words in regard to the translation. The English rendering is satisfactory, being both accurate and smooth, despite a few, but not important, infelicities. Certain changes deserve mention. All the technical directions as to methods are now gathered at the end of the volume, an arrangement much more convenient than that still followed by Professor Stöhr of scattering them through the volume, making

it difficult to find any special "direction" wanted. The editor, Dr. Alfred Schaper, who was formerly Professor Stöhr's first assistant, and at present Demonstrator of Histology and Embryology at the Harvard Medical School, has added a valuable chapter on the placenta, and enlarged that upon the uterus, thus making good the only serious deficiencies in the sixth German edition, from which the translation was made. On the technical side the entire absence of any suitable account of microtomes will be felt, especially in America, as a defect not readily excused. This omission should be repaired before another edition is issued.

We are glad to recommend this work very cordially to both practising physicians and medical students. The publishers' part has been admirably done; the type is clear and attractive and the delicate illustrations have been beautifully printed.

Professor Huber's book is especially arranged for the use of his own classes in the University of Michigan, and for that use it appears admirable. It gives specific directions how to make a large series of preparations, and gives for each preparation excellent rules for observing and understanding what it should show. It is arranged in twenty-five lessons, and five or six preparations are treated in each lesson. The lessons are followed by a collection of very excellent directions concerning methods, which are clearly and often felicitously presented. We notice some omissions, and are surprised that no mention is made of microtomes. This fact, together with the offering the students several preparations at each exercise, suggests that the author's standard for students is not very high, for experience shows that two hours is the extreme minimum of time, for a student to master a single preparation in the laboratory.

Mr. Clarkson's volume is beautifully made, and offers the best and most comprehensive set of colored illustrations of histological subjects, known to us. The figures are very good, and are remarkably uniform in merit. They are distributed over eighty-eight plates, which are scattered through the volume, and are all lithographic reproductions of original drawings made by the author,—except nine figures contributed by friends.

The book includes a well-written text, which treats of both methods and of the preparations. The treatment of the urogenital system is inadequate, and that of the nervous system is almost perfunctory. The other parts of the text are much better than these two.

The limitations of the book are very sharply marked, for the author deals only with the ordinary text-book and laboratory knowledge, and is apparently almost wholly ignorant of the literature of histological research, and quite unaware that in order to write such a work as he has undertaken, he should first study one or two thousand of the histological publications of recent investigators.

C. S. M.

The Practice of Medicine. By HORATIO C. WOOD, M.D., LL.D., and REGINALD H. FITZ, A.M., M.D. Philadelphia: J. B. Lippincott Co. 1897.

The preface tells us that this volume "is the outcome of an attempt to view the practice of medicine simultaneously from the pathologic and therapeutic points of view. Whilst each author has written certain determinate portions of the book, there have been such careful joint consideration and discussion of the various subjects that there is a common respon-

sibility, except in the very few places where final difference of opinion is indicated in the text, either over initials or by the use of the pronoun 'I' instead of 'we.'

After reading this opening statement we were tempted to turn to the articles on typhoid fever and appendicitis, expecting, as was the case, to find the "I" instead of "we" in the former in regard to the use of oil of turpentine in the treatment of intestinal ulceration, and in the latter the different initials attached to differing views as to surgical interference in appendicitis.

In general, it is rather surprising that two doctors collaborating upon a work of this kind should disagree as seldom as do Drs. Wood and Fitz. It is scarcely necessary to state that Dr. Wood is Professor of Therapeutics and Clinical Professor of Nervous Diseases in the University of Pennsylvania, and that Dr. Fitz is Professor of Theory and Practice and was formerly Professor of Pathological (not Pathologic) Anatomy in Harvard University. In spelling, apart from the title-page, the two authors seem to have agreed upon the newer Philadelphia terminations.

Dr. Wood's and Dr. Fitz's training and experience as teachers and consultants have well fitted them for writing a book on the Practice of Medicine, and the work which they have produced attests this. Collaboration, on the other hand, has its drawbacks as well as its advantages. In places one has to read closely to be sure of the intended meaning.

The contents of the volume of 1088 octavo pages are divided into six sections. Under Section I come General Diseases, in six chapters; under Section II, Diseases of the Nervous System, in seven chapters; under Section III, Diseases of the Circulatory Apparatus, in four chapters; Section IV, Diseases of the Respiratory Apparatus, in three chapters; Section V, Diseases of the Digestive Apparatus and of the Peritoneum, in five chapters; Section VI, Diseases of the Urinary Apparatus, in two chapters. There is a good general index.

In printing the book, a second sub-heading on the top of the right-hand page would have facilitated reference, for example, on the left-hand page, General Diseases; and on the right-hand page, Infectious Diseases—Typhoid Fever.

Under the treatment of Exophthalmic Goitre we miss any reference to extract of the thymus gland. For the diagnosis of typhoid fever no reference is made to the serum test, but this was less in evidence when the chapter was written than at present. In the treatment of typhoid fever it is stated that "alcohol in some form should be used in every case from the beginning." The indications laid down for its increase or diminution are sound, as is the dietary recommended. The external use of cold water, including baths, is recommended.

Plague receives less than a page. In view of its activity in Asia Minor, in Persia and in China within the last twenty-five years, it deserves more respectful consideration. On the other hand, in view of the present generally accepted relations of the serum treatment to diphtheria, the space devoted to the local treatment of this disease might have been condensed. We doubt the implied statement that diphtheria antitoxin is responsible for albuminuria.

In Malaria we should consider the administration of smaller doses of quinine immediately after the par-

oxysm more effective and less disturbing than the exhibition of larger doses, eight to ten hours, and four to five hours before the paroxysm, as recommended.

Under Cholera we find no reference to Haffkine's work in India.

Under the head of Hereditary Syphilis, the possibility of congenital or intrauterine infection seems to be correctly recognized by the authors, although Kassowitz is quoted to the effect that "the syphilitic virus does not pass through the vascular walls dividing the fetal from the maternal blood."

Incision, or even a resection of the rib, is, we are glad to see, suggested as proper in purulent pericarditis.

The book is characterized by a severe absence of all pictorial illustrations, if we except a few diagrams in the chapters devoted to Diseases of the Nervous System. The temptations offered by the newest micro-organisms and by the oldest temperature charts, have been resisted. We are almost inclined to offer much thanks for this relief. Good wine needs no such bushes.

Handatlas der Anatomie des Menschen. Atlas of Human Anatomy. With 750 illustrations, some colored, with text. By WERNER SPALTENHOLZ, Professor at the University of Leipzig, with the support of PROFESSOR HIS. Volume II, Part I. Leipzig: P. S. Hirzel. 1896.

We have before us the first part of the second volume of this remarkable atlas, treating on the muscles. It begins with some diagrammatic figures, making clear the regions into which it has been thought necessary to divide the surface of the body, and then come the muscles. The style of illustration is the same as in the previous parts, with colored muscles. They are truly admirable as works of art, and at the same time convincing as true anatomy. The muscles of the face and neck deserve particular notice. The platysma is admirably shown as it is when well developed. A very instructive picture is that showing the muscles of the mouth dissected from the inside. There are some beautiful dissections of the fasciæ, among which we may mention one of the back of the thigh, revealing the relief of the muscles through the transparent fascia. The appendages of the muscular system, namely, the bursæ and the synovial sheaths, are also duly considered.

The only criticism we are inclined to make is on the very small number of frozen sections. In fact, there is, we believe, in this part but one, and that borrowed from Merkel.

T. D.

Hygienisches Taschenbuch für Medicinal und Verwaltungsbeamte, Aerzte, Techniker und Schulmänner. Von DR. E. VON ESMARCH, Prof. Hygiene, Univ. Königsberg. Berlin: J. Springer. 1896.

This hand-book is compact, practical, concise and thoroughly adapted to the uses for which it is intended as a reference manual for health officers and medical men generally. The method of treatment of the subject of hygiene employed in this work is that of brief, concise definitions, principles, axioms and formulæ relating to public health.

The subjects treated are the following: air, soil, water, the hygiene of dwellings and their construction, lighting, ventilation, heating, the removal of household waste, schoolhouses, hospitals, prevention of infectious diseases, and disinfection.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, FEBRUARY 4, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE ANNUAL REPORT OF HARVARD COLLEGE, 1895-96.

In the portion of this report devoted to the Medical School, President Eliot characterizes as the most important event at that school during the year 1895-96 the decision of the Faculty to require, after the year 1900, that all candidates for admission to the school must present a degree in Arts, Literature, Philosophy, Science, or Medicine, with the exception of persons of suitable age and attainments who may be admitted by a special vote of the Faculty in each case. This step, he states, will place the Medical School, after 1900, by the side of the Divinity School, the Law School, and the Graduate School, which already require for admission a degree in Arts, Literature, Philosophy, or Science. After that year there will therefore be four graduate departments in the university. He reminds us that when the Graduate School was instituted there was no other graduate department, and its name was distinctive; but the word graduate is now applicable to two other departments, and will soon be applicable to three.

He dwells upon the increasing importance of laboratory service in medical and surgical practice as illustrated in the new instruction given in the Chemical Department on the clinical examination of the blood. The Bacteriological Laboratory first makes the diagnosis in a possible case of diphtheria, and then supplies the remedy if it is needed. The Laboratory of Hygiene has demonstrated useful truths in regard to various liquid malt extracts and certain lithia waters. The laboratories of the Medical School, however, not only supply important aid to clinical medicine and surgery, but are also active in advancing medical knowledge.

He refers to the munificent gift of Mr. George F. Fabyan on the 1st of July last, establishing another professorship in the Medical School which cannot but prove to be of the utmost value—a professorship of

Comparative Pathology. This immense subject includes, of course, human pathology; but it ranges over the whole pathological field among the animals which associate with mankind, or furnish food to the human race, or do good or harm to the crops or creatures on which men feed.

Prof. Theobald Smith, who was transferred from the department of Applied Zoölogy to this new Fabyan Professorship in the Medical School continues to occupy the convenient laboratories previously fitted up for him at the Bussey Institution.

In this connection the President advocates a reconstruction of the School of Veterinary Medicine upon a larger plan, by which with the foundation of a professorship of Comparative Anatomy and another of Comparative Physiology, a department of Comparative Medicine might be organized. There should, he considers, be the closest affiliation between the Medical School and such a School of Comparative Medicine. The two schools should, in his opinion, be placed under the direction of a single Faculty of Medicine—the two groups of students being kept distinct, and each group being governed by a dean and an administrative board. The experience of the Faculty of Arts and Sciences, under which Harvard College (the Academic Department proper), the Lawrence Scientific School and the Graduate School are administered, is, the President thinks, directly applicable to this new suggestion, and is highly encouraging for its successful working.

Professor Smith gave during the past year a course of lectures, the first of its kind, to the students of the Veterinary School on the "Etiology and Hygiene of the Infectious Diseases of the Domestic Animals." The course embraced a discussion upon the following subjects: Causation of the infectious diseases of animals; bacteria and their relation to disease, morphology and biology; the pathogenic action of bacteria, natural immunity, predisposition, acquired immunity, including the uses of antitoxins; hygienic surroundings and the methods by which these diseases are communicated, as well as those which must be undertaken to prevent their spread; antiseptics, disinfectants, sterilization, and protective inoculation. This was followed by a consideration, at length, of the contagious and infectious diseases of swine, sheep, horses, cattle, dogs, turkeys and fowls.

In this connection the Dean of the Veterinary School points out that when one considers that all of the animals with which we live in more or less close contact, and from which an important part of our food supply is derived, are not uncommonly affected with diseases which not only easily spread among themselves, but are now known to be communicable to man, always with bad, and oftentimes with fatal results, it will be well understood that the importance of the study of comparative medicine can scarcely be overestimated.

The President emphasizes again the great need of the Medical School for one or two halls of furnished

chambers with low rents, not too remote from the school building, and constructed with every sanitary precaution and every means of health, such as good baths and good means of heating and ventilation. Near these halls a dining-room conducted on the plan of the Foxcroft Club at Cambridge, would be very serviceable. Medical students, he truly says, who have little money undergo more physical hardship and exposure than any other class of students; and yet less care is taken of them. No benefactions have, as yet, made their lives safer and easier.

The report of the Dean of the Medical School goes more minutely into the administration of the school during the past year, and the changes which have taken place. The first class under the required four years' course of instruction graduated in June, 1896, and numbered 101, of whom 35 received the degree *cum laude*. The whole number of students in attendance during the year was 552. During the last three years there has been once more, after a somewhat continuous decline, a steady increase in the number of college graduates among the matriculants: in the year 1893-94 there were 27 per cent., in 1894-95, 35 per cent., in 1895-96, 41 per cent. Some of the laboratories of the school are overcrowded, and some relief must before long be found. Notwithstanding the increasing attendance—partly perhaps in consequence of that, and partly in consequence of expenses for electrical lighting, ventilation, and other improvements in the school building—there is again a deficit in the annual accounts of the school, and the reserve fund has been reduced from \$89,000 in 1893 to \$73,000 in 1896. With the growth of laboratory instruction and a constantly increasing corps of teachers, medical education, as given in a school of the highest rank, becomes more and more costly. In this it offers a strong contrast to the education given in a Law School or a Divinity School.

The number of students at the Dental School is increasing, during the past year 103 were in attendance, of whom 20 were in the Senior Class, 36 in the Junior Class, and 47 in the Freshman; the graduating class was the largest in the history of the school. The Medical Faculty having abolished the course in General Chemistry which dental students have hitherto attended, the Dental School has been obliged to provide a chemical laboratory of its own. The range of operations of the Dental Infirmary has been increased. Artificial noses were supplied in cases where the natural nose had been lost by accident or disease. Fractured jaws, requiring complicated appliances, were successfully treated, and patients with cleft palate and incapable of articulate speech had their speech restored and their appearance greatly improved. The service of the Infirmary is gratuitous. The Dental School is now occupying every available part of the building at present in use.

The Dean reports that the school is crowded and hampered in its work, which the Faculty is conducting under adverse conditions, at the same time main-

taining through the Infirmary a great and worthy charity.

In the Veterinary School three new courses of instruction were added during the year: one in Comparative Pathology, one in the Etiology and Hygiene of the Infectious Diseases of Animals, already referred to, and one in Practice. This school has always hoped to be able to maintain a free clinic for the gratuitous treatment of suffering animals whose owners could not afford to pay for treatment. Such a clinic is at once a charity and a means of instruction. During the past year this hope has been fulfilled in large measure through the generosity of the Visiting Committee of the school, who have provided a building at their own charge for three years for this purpose. This charity hospital for animals was opened about a year ago. Here is a grand opportunity for all lovers of animals to aid in a good work twice blessed. We commend it most especially to those tender and hustling souls whose energies are now devoted to the protection of the guinea-pig and the frog from the assiduity of the physiologist. Let them subscribe and induce others to subscribe to the charity hospital or free clinic for sick and wounded animals. Being free from all public agitation and sensationalism, such action commends itself as a quick but at the same time most effective way of being useful to man's dumb servants, companions and dependants of the animal kingdom.

THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE THREATENED.

THE Appropriation Committee of the House of Representatives in Washington have now under consideration a proposal to transfer the Library of the Surgeon-General's Office from the Army Medical Museum to the New Library of Congress; and Mr. Cannon of Illinois, the Chairman of the Committee, proposes to have this inserted in the Sundry Civil Appropriation Bill. He does not propose at present to transfer the management of the library from the Medical Department of the Army to the Librarian of Congress, but this will almost certainly follow in a year or two. If this proposal should succeed, the result would probably be a cutting down of the Appropriations for the Medical Library, reductions in the force of its cataloguers and indexers, and a great diminution in the future utility of the library to the physicians of the United States.

There is no time to lose if the members of the medical profession desire to express their opinions and use their influence to prevent serious damage to their interests. They should at once put themselves in communication with their representatives in Congress and with any of their acquaintances who may have influence with those representatives.

This is a matter in which the best interests of the medical profession subserve the best interests of the general public welfare. The profession has very

lately been enjoined by a most distinguished adviser not to neglect to concern itself with public affairs. Here and now is presented a very suitable opportunity to act upon this excellent advice.

MEDICAL NOTES.

ZYMOTIC DISEASES IN DUBLIN.—Scarlet fever, measles and whooping-cough are epidemic in Dublin, and the capacity of the hospitals is seriously overtaxed.

A MEDICAL BARONET.—Dr. Douglas Powell, physician extraordinary to the Queen and physician to the Middlesex Hospital, was created a baronet at New Year's.

TRAUMATIC TETANUS TREATED BY HYPODERMIC INJECTIONS OF ANTISEPTICS.—Two cases are reported in recent numbers of the *Lancet* and *British Medical Journal*, of traumatic tetanus successfully treated by hypodermic injections of carbolic acid and corrosive sublimate respectively.

MEMORIAL OF BARON HIRSCH.—The widow of Baron Hirsch has presented the Pasteur Institute in Paris with 2,000,000 francs as a memorial of her late husband. It is also reported that she has presented 80,000 pounds for the establishment of a seashore hospital for the treatment of children afflicted with tubercular disease.

NURSING BOTTLES AND THE BABIES' HEALTH.—The following ordinance has been passed by the Board of Health, of Buffalo, N. Y.: "And it shall be unlawful for any person or persons to use or to engage in the sale of any bottle, mechanism or other device for the artificial feeding or nursing of infants or children under three years of age, which has connected therewith a rubber tube, hose or such contrivance."

A BELLICOSE SURGEON.—Lepelletier had occasion recently to address the graduates of the military school at St. Cyr, France, and called upon them "to arise in their might and as surgeons of the honor of France, perform *rhinoplasty* upon the territory of their fatherland, and restore the flap of living flesh so brutally severed by the conquering Germans!"—*Journal of the American Medical Association*.

THE DEADLY NICOTINE.—In a book of travels written by a Mr. Barrow we find this interesting bit of information: A Hottentot was seen to apply the short end of his wooden tobacco pipe to the mouth of a snake when the reptile was darting out its tongue. Death was instantaneous, the effect almost like an electric shock; with a convulsive motion that lasted only for a moment the snake half untwisted itself and then became still. And upon examination the muscles were found to be so contracted that the snake felt as hard as if it had been dried in the sun.—*Harper's Round Table*.

Does this incident point most strongly to the susceptibility of the reptile or the toughness of the Hot-

tentot? Would tobacco be indicated in delirium tremens?

DISINFECTION OF THE MAIL.—Nine sacks of mail from India came into New York Harbor last week, and were taken off the steamer at quarantine for disinfection, in view of the bubonic plague that is devastating Bombay and the far East. Dry heat was employed. Chambers have been provided on the new quarantine boat, where treatment can be given by heat, steam, formalin, or bichlorid of mercury.

A MEDICAL PRESIDENT.—M. Adolphe Deucher, who has just been elected president of the Swiss Confederation for the ensuing year by an almost unanimous vote, is a member of the medical profession. He was born in 1831, and was actively engaged in medical practice till 1879, when he retired in order to devote himself entirely to political life. He had, however, for some twelve years before that been a member of the Swiss Parliament, in which, though a staunch Catholic, he played a conspicuous part as a radical.

APPOINTMENT OF A FIRST-ASSISTANT PHYSICIAN AT THE SHEPPARD ASYLUM, BALTIMORE.—At a special meeting of the Trustees of the Sheppard Asylum, held Thursday, January 28th, Dr. Charles M. Franklin, of Lancaster, Pa., was elected to the position of first-assistant physician. Dr. Franklin is a graduate of the Franklin and Marshall College, and in medicine at the University of Pennsylvania. After taking a term of service in one of the general hospitals in Philadelphia, he served for a time in the Friend's Asylum at Frankford, resigning to go to Europe, where he spent two years in study at Vienna and Berlin. Upon returning he was shortly afterwards appointed assistant physician at the men's department of the Pennsylvania Hospital for the Insane, Philadelphia, where he served for over two years, resigning to enter upon private practice in Lancaster.

THE BRITISH ARMY MEDICAL SERVICE.—It is reported on good authority that only two applicants have appeared for a competitive examination for the British Army Medical Service, which is to be held in February, to fill thirty-six vacancies. The War Office is stated to be sending out "into the highways and byways for the maimed, the halt, the lame, and the blind" in order that their little wedding in February shall be furnished with some sort of guests. Come what may, says the *Medical Press and Circular*, the army medical authorities will not give the minutest concession to the "d——d doctors" unless Parliament forces them to do so. Let us hope that they will have to do so.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, February 3, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 113, scarlet fever 38, measles 51, typhoid fever 11.

THE SALEM HOSPITAL.—At the recent annual meeting of the corporation of the Salem Hospital, a report was read showing that 350 patients were treated at that institution during 1896.

THE APPROPRIATION FOR THE MASSACHUSETTS CATTLE COMMISSION.—The bill appropriating \$250,000 for continuing the work of the Massachusetts Cattle Commission in exterminating tuberculosis and other contagious diseases among animals, has been passed to be engrossed by the House of Representatives, in spite of opposition on the part of the farmers.

THE MASSACHUSETTS ASSOCIATED BOARDS OF HEALTH.—The annual meeting of the Massachusetts Associated Boards of Health, was held January 28th at the Parker House, Boston. Dr. H. P. Walcott presided. Professor W. T. Sedgwick of the Massachusetts Institute of Technology read a paper on the "Protection of Public Milk Supplies from Pollution." Officers were elected as follows: President, H. P. Walcott; Vice-Presidents, S. H. Durgin, S. W. Abbott; Secretary, Edwin Farnham; Treasurer, James B. Field.

NEW YORK.

PRESIDENT CLEVELAND ADDRESSES THE NEW YORK ACADEMY OF MEDICINE.—The exercises of the semi-centennial celebration of the New York Academy of Medicine on January 29th were carried out in accordance with the announced programme, and everything passed off in the most satisfactory and enjoyable manner. Carnegie Hall was filled with a cultured audience, and the occasion was an inspiring one. After addresses by Dr. Bryant, President of the Academy, and by Drs. Purple and Sayre, two of its founders, came the oration of ex-President Jacobi, and the exercises were concluded with the address of President Cleveland, who had come on from Washington for the occasion, accompanied by Secretary Lamont and Surgeon-General Sternberg. In the course of his remarks Mr. Cleveland spoke as follows in regard to the political obligations of members of the medical profession: "If laws are needed to abolish abuses which your professional investigations have unearthed, your fraternity should not be strangers to the agencies which make the laws. If enactments already in force are neglected or badly executed, you should not forget that it is your privilege and duty to insist upon their rigorous and honest enforcement. Let me also remind you of the application to your case of the truth embodied in the homely injunction, 'If you want a job well done, do it yourself.' If members of your profession were oftener found in our National and State legislative assemblies, ready to advocate the reformatory measures you have demonstrated to be necessary to defend your brotherhood against flippant and sneering charges of impracticability, the prospect of your bestowal upon your fellowmen of the ripened results of your professional labor would be brighter and nearer." After the conclusion of the exercises at Carnegie Hall a reception was held at the Academy of Medicine Building.

THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.—At the annual meeting at Albany of the Medical Society of the State of New York, which, on account of special circumstances, was held a week earlier than usual, the following officers were elected: President, Dr. Seneca D. Powell, of New York; Vice-President, Dr. Lucien Howe, of Buffalo; Secretary, Dr. F. C. Curtis, of Albany; Treasurer, Dr. Charles H. Porter, of Albany.

DEATH OF DR. RICHARD J. HALL.—Dr. Richard J. Hall, a son of the Rev. Dr. John Hall, of the Fifth Avenue Presbyterian Church, died recently of appendicitis at Santa Barbara, Cal. Dr. Hall was forty-one years of age, and was graduated from Princeton College in 1875, and in 1878 from the College of Physicians and Surgeons. After pursuing his professional studies for a time in Vienna, he returned to New York, where he received an appointment on the attending staff of the Presbyterian Hospital, and soon won an enviable reputation as a surgeon of unusual ability. Some years ago, on account of the development of pulmonary trouble, he was obliged to remove to Santa Barbara. As a result of his residence in a more genial climate his health gradually became re-established, and he was after a time enabled to resume the practice of his profession. He leaves a wife and two young daughters.

DEATH OF DR. McNAMARA.—Dr. Lawrence J. McNamara, a graduate of Bellevue Hospital Medical College in the year 1882, died on January 28th. He early won distinction as a pathologist and bacteriologist, and on the opening of the Carnegie Laboratory, in connection with the Bellevue Medical School, was appointed one of the instructors in that institution.

THE MORTALITY OF NEW YORK IN 1896.—The annual bulletin of the State Board of Health shows the average daily mortality in the year 1896 to have been 340, against 336 in 1895. The highest death-rate was, as usual, in July, and the lowest in November. Influenza was epidemic early in the year, and is accredited with about 3,000 deaths. The mortality from scarlet fever was the smallest in ten years, while that from measles was the largest. The number of deaths from pulmonary tuberculosis was about the same as usual, a little over 13,000.

THE BLIZZARD INCREASES THE DEATH-RATE.—In the city of New York the intense cold of the early part of last week, followed by the severest snow storm of the season, had the effect of slightly increasing the mortality, which has been phenomenally small for this time of the year. For the week ending January 30th the number of deaths recorded was 758, against 703 in the week ending January 23d and 700 in that ending January 16th. The highest death-rate is principally due to consumption and pneumonia, the deaths from which increased respectively from 83 to 120 and from 77 to 109. With the exception of that from diphtheria, which averages about 30 deaths per week, the mortality from contagious diseases has for

a number of months been insignificant. Thus, in the week ending January 30th there were but two deaths from influenza, seven from scarlet fever, four from measles, and one from typhoid fever.

Miscellany.

DANIEL MARCH, JR., M.D.

RESOLUTIONS OF THE EAST MIDDLESEX DISTRICT MEDICAL SOCIETY.

WAKEFIELD, January 20, 1897.

Whereas, In the all-wise providence of the great Ruler of the universe, our most highly esteemed associate, Dr. Daniel March, Jr., has been suddenly stricken down and taken from our midst, it is hereby

Resolved, That the members of the East Middlesex District Medical Society deeply and sincerely mourn the loss of its officer and member. As its President, he was able and efficient in his office; as a member, he was ever a willing coadjutor, wise councillor and loyal friend. As a physician, he was worthy and well-qualified, just and upright in the highest degree in his relations with his fellow-practitioners, unselfish, courteous and kind. He was deeply beloved by his constituency for his skill in his profession, his generosity, his sympathy and helpful spirit. As a citizen and a man among men, he was valued for his true friendship, his unswerving integrity and his sacred honor. The members of this Society will ever cherish the memory of our deceased brother, and hold in emulation his character and record.

Resolved, That a copy of these resolutions be sent to the family of our deceased President, extending to them the heartfelt sympathy of our Society, and also that the same be spread upon the records of the Secretary.

FRANK W. GRAVES, M.D.,
SETH W. KELLY, M.D.,
CHAS. C. ODLIN, M.D., } Committee.

EDWARD P. ELLIOT, M.D.

BOSTON, January 21, 1897.

In the death of Dr. Edward P. Elliot, Assistant Superintendent of the Danvers Lunatic Hospital, the Medico Psychological Society has sustained a loss which its members can but view as personal.

His unassuming, modest bearing, genial companionship, and cultured intellect commanded the regard of all who came in contact with him.

His methodical application to his duty, his faithful devotion to his obligations, and his loyalty to superior officers were traits which characterize a true knight, whose death always leaves a permanent void in the ranks.

His rare mental gifts, quick perception, retentive memory, logical powers, and scientific inclinations admirably fitted him for the good work he has done, and gave rich promise of ultimate eminence in his profession.

But alas! these divine faculties, deprived of full exercise by physical infirmities extending over a period of several years, are now extinguished to us by the untimely claims of Death. Therefore:

Resolved, That this, our estimate of his ability and worth, be entered upon the records of this Society, as an expression of our feelings of deep personal affliction.

Resolved, That the Secretary be requested to make a copy of this record, and transmit the same to Dr. Elliot's bereaved father, with the assurance that we sorrow for him in his loss, and sympathize with him in his loneliness.

CHARLES W. PAGE,
PHILIP COOMBS KNAPP,
ROBERT T. EDES, } Committee.

Correspondence.

LETTER FROM ROME. PUBLIC HEALTH IN ROME.

ROME, January, 1897.

MR. EDITOR:—During a short stay in Rome, I have been enabled, through the kindness of Dr. Tito Gualdi, Sanitary Director, to examine some of its hygienic arrangements, and have found them most admirable. The same laws as to public health are found throughout the whole of Italy, but the perfection of detail depends upon the individual city.

Each city has an elected town council as its legislative body. This council elects in turn a junta, consisting of a syndic or mayor, and a number of *assessori*. The mayor is the president of the junta, and the *assessori* are practically deputy mayors, each *assessore* having in charge some particular department, such as finance, or public health. The junta is the executive body of the city. The *assessore* of public health has, however, no power over the practical details of the health department. These are in the hands of the sanitary director, who is elected by the town council and must be approved by the central government. The sanitary director not only attends to contagious diseases, but has also the care of the treatment of the poor. For this purpose, in Rome, are appointed (by competitive examination) eighteen district physicians and seventeen *u-turni* or physicians for night calls. There are, also, six *neeroscopi* through whose hands all death certificates must pass. There are located in this city, and under the sanitary director, five maternity hospitals. If a poor woman be about to become a mother, she is taken to one of these hospitals, delivered, and returned to her home, in uncomplicated cases, in twelve days. It is rather uncommon, at present, for any poor woman to be confined in her own home.

In the case of contagious diseases, the laws are very strict and very rigidly observed. Each practising physician of the city is given a book containing a large number of coupons, with spaces for the name of the patient, residence, etc. When he meets a case of contagious disease, he must detach two of these coupons, and personally present them without envelope, one to the syndic and one to the sanitary director. They, separately, must report the case to the central government. The idea is, that the suppression of cases, through favoritism or other causes could hardly occur, since each official acts as a check on the other. The physician does not enter the disease on his coupon (as the coupon is open to view), but simply numbers it, leaving on the back cover of his book a number corresponding to each of the prescribed diseases. This method is in vogue all over Italy, and is called "denouncing" the patient.

Cholera is the most dreaded of all diseases, but is now practically extinct in Rome, owing to an excellent water system, great care in bacteriological examination, and excessive precautions on the part of the health authorities in all suspected cases. There are two laboratories under the sanitary director, one for bacteriological examinations of all kinds, and the other for chemical analyses. The chiefs of these laboratories must be men well known in their special line of work, and they must be confirmed in their appointment by the State. Variola is of rare occurrence, owing to a very general vaccination. The law requires that each child shall be vaccinated before it is one year old, and revaccinated in its eighth year. There are two penalties for violation of this mandate. The first is that the unvaccinated child cannot enter any school, either public or private. In Boston, a child cannot enter any public school without having been previously vaccinated, but may be sent with impunity to any one of our numerous private ones. Thus, their law is stricter than ours in that particular. They have, besides, a second penalty, which is, that unless a child be vaccinated at the times prescribed,

he cannot, in after years, be eligible for any public office. This, to an Italian, is practically a loss of citizenship.

Tuberculosis is placed among the diseases to be denounced. When a notification of a case of tuberculosis is received, the house is visited by a medical sanitary inspector. He gives complete instructions to the attendants or family. The attending physician is obliged to see that all handkerchiefs, nightdresses, bed linen, etc., are thrown into a receptacle containing proper disinfectants. At regular intervals the disinfectors from the lazaretto call and remove all soiled articles, thoroughly sterilize them, then wash them and return them to the owners. This is done at the municipal expense in the case of poor people. Others pay according to their means. It is forbidden to wash any article belonging to a tuberculous patient outside the lazaretto. After a death from tuberculosis, the rooms and furniture are disinfected in a manner to be hereinafter described. A complete record of all houses in which tuberculosis has occurred, is kept at the central health office, so that any one about to hire or buy a house, may there learn its full history.

In some of our American cities, notably New York, similar precautions are taken. In Boston, however, where tuberculosis kills more people than all the other germ diseases combined, we do nothing. If we have an excessive mortality, we complacently attribute it to the prevalent east wind, and so plod along in our mediæval way. O modern Rome! O ancient Boston!

All cases of contagious diseases are supposed, of necessity, to go to the lazaretto. Special permission to remain at home may, however, be granted at the discretion of the sanitary inspector. In such cases the family physician is directly responsible to the health authorities for the carrying out of all proper precautions and must conduct the case under their supervision.

There are two corps of disinfectors. One stationed at what, for convenience, I shall call the central building; the other at the lazaretto. Those at the lazaretto, however, are in a separate building at one of the gates of the courtyard, and are exposed in no way to the dangers of the contagious hospital proper. The men at the central building have apartments corresponding somewhat to the ground-floor of one of our fire-engine houses. These consist of three large, well-lighted rooms with concrete flooring. One of these rooms is the office, in which all records are kept. Then comes the main room which contains a number of small carts, some of them small enough to be dragged by a single man, and others built for two men. Next in order is a room containing boxes and wardrobes for clothing, sterilized sheeting, etc., and a shower bath.

When the men arrive in the morning, they strip off their clothing, and don a fatigue uniform of blue cloth, only to be worn while at work. Then, they get their respective carts ready for the day's work. The carts contain a large tub which holds a measured quantity of water, concentrated solutions of corrosive and other disinfectants in bottles, a glass graduate, a large number of brushes of different sizes, a strong metal scraper for walls and floors, a heavy broom, which comes apart for convenience in packing, a thick swab of short broom canes, shaped like an inverted cone, for swabbing water-closet bowls, a sterilized linen suit and sterilized shoes. Attached to the outside of the cart are the brush poles which are too long to be conveniently packed away. The suit consists of long, loose linen stockings which draw over the foot and are tied to the upper part of the thigh, a long blouse or coat which comes nearly to the knees and which is tied in at the wrists and neck, besides being lapped over, and closely fastened all the way down the front, a linen hood falling over shoulders and having a face strap across the mouth and moustache, and a pair of large shoes. The shoes deserve a passing notice. It is considered here that shoes of all kinds are the greatest carriers of infection. It is enjoined then, that the men, when about to enter an infected house, shall remove their shoes at the entrance, put on the sterilized over-suit and then the shoes provided by the department. These are a large, clumsily-made shoe with thick wooden soles and heels

and a strong cloth top. It is found that these can be sterilized as easily and as thoroughly as the suit. Each man is obliged to return to the central office after every disinfection, and before starting again must provide himself with freshly sterilized suit, hood and shoes. No over-suit is used twice without resterilization.

When a disinfection is to be done, the lazaretto men are notified by telephone, so that they may be at the appointed house at the same time as the others. Then, before starting, a record is taken at the central office of the place to be visited, the hour of starting, and the men detailed; on the return of the men, a further record is made on the same blank of the hour of return, the apartments disinfected, the articles removed for disinfection, the amount of disinfectants used, the kind of disinfectants and any other details which may be necessary. This blank is afterwards verified by the visit of an inspector, who travels from place to place on a bicycle. After his verification has been obtained, the record blank is filed in the department. When the work of the day is concluded, the men wash face and hands in a corrosive solution, strip to the skin, put away their fatigue uniforms, step under a shower bath, don their street costumes and go home.

The method of disinfecting a room is worthy of consideration. The central and the lazaretto men meet at any house designated. The central men, having put on their sterilized suits, proceed to the infected apartment. If the floor be carpeted, they first spray with corrosive solution, 1 to 500, combined with chloride of sodium, so that no dust may arise. Then the carpet is removed, the floor being continually wet under it during the process of removal. If a bare floor exist, it is immediately drenched with a plentiful supply of 1 to 3,000 corrosive, combined with hydrochloric acid. All carpets, bedding, mattresses, portières, curtains, clothing or anything of like nature are rolled up in sterilized sheeting and given to the lazaretto men, to be removed by them and treated at their own building. The central men then thoroughly drench the walls with corrosive (1 to 500) and chloride of sodium. This drenching is done with a small hand-pump which should have been enumerated with the contents of the cart. After the drenching, a vigorous scrubbing takes place, and, if need be, a vigorous scraping also. Each chair is taken to the tub and thoroughly scrubbed with the solution. Stuffed furniture is treated with the corrosive and sodium chloride solution, which they consider harmless. Metal articles, such as brass beds, are rubbed over with a phenic-acid solution. Water-closet bowls are swabbed out with slaked lime. Landlords are then obliged to paint, paper and whitewash the rooms at their own expense.

The thought occurred to me, that perhaps our people might object at first to such thorough measures, and I, therefore, asked Dr. Gualdi whether he ever met with opposition. "Oh, yes," said he, "we used to meet with clubs in the beginning, but we persevered, and now the people send for us and are willing to pay. This is notably the case in tuberculosis, where we often disinfect a number of times during an illness."

When the men employed at the lazaretto disinfecting plant arrive in the morning, they enter an outer room, strip to the skin, pass through a second room into a third, where they put on a blue blouse and pantaloons which are worn all day. They receive a freshly-sterilized suit every morning. When they are ready to leave at night, they strip in the inside room, wash face and hands in a corrosive solution (1 to 1,000), then pass into the middle room, where they take a shower bath of fresh warm water, resume their street dress in the outer room and go home.

The lazaretto disinfecting plant contains two steam boilers, a receptacle for phenic-acid solutions, a stone vat for corrosive solutions, arranged so that the articles may be thrown into it in the infected apartment and removed on the other side of the partition, a small, tight apartment for sulphur fumigations, various vessels for cleansing purposes and a complete washing and ironing department.

They place great reliance on their steam sterilizers and work them scientifically. According to Geneste, twenty-

five minutes at 100° to 120° C. were only required in these boilers to destroy all germs. After a number of experiments, however, they have come to the conclusion, in Rome, that sixty minutes should be given to each sterilization. Attached to each boiler is an instrument which records on a chart the number of minutes consumed during each sterilization and the pressure during that time. There are, also, two instruments, either one of which is used for determining the degrees of heat. One is a thermometer which is placed in the very centre of the articles to be disinfected. This is so arranged that when the column of mercury pushes up to 120° C., a metallic circuit is completed and a bell is rung. The other is an ordinary spring clothes-pin, jaws pressed apart and held so by a clamp composed of an alloy which fuses at any point from 90° to 120° C., according to its composition. When the desired heat is reached, the clamp dissolves and releases the pin, which springs back into position and rings a bell. As soon as the bell announces that the maximum heat desired has reached the centre of the mass of bedding, or whatever may be in the boiler, the recording apparatus is attached and the chart must then record a duration of sixty minutes at a uniform pressure of eight atmospheres. Whenever handkerchiefs, bed linen, nightdresses or any articles for personal use are spotted with fecal matter, sputum, blood or pus, they are not only treated with steam, but the spots are carefully scrubbed in various disinfecting solutions. Permanganate of potassium is frequently used for this purpose. Many of such articles are thrown into the corrosive vat (1 to 500) and there kept for six hours. They are then put into vessels constantly filled with fresh, running water. They are afterwards bleached in vessels containing soda lye, heated to 100° C., and finally washed in large iron tubs, attached to a steam belt, and so arranged that they have a churning and an oscillating movement at the same time. Shoes are dipped into a phenic-acid solution, and great care is taken that the soles are thoroughly treated. Sulphur fumigations are reserved for valuable furs, and such things as cannot be treated in any other way.

The lazaretto proper is under the care of the Sisters of Charity. No hired attendants are allowed within its walls. The nuns, themselves, do everything from the lowest kinds of menial work to the highest form of nursing. Those nuns who have patients under their care are necessarily quarantined until their wards are empty. The physicians also live in the hospital and remain isolated during their term of duty.

As with us, they treat, principally, diphtheria and scarlatina. Measles and typhoid are, however, frequently under treatment. For both of these diseases, the disinfecting regulations are enforced. Glanders is sometimes met, and for this there is a special disinfection of apartment, consisting of a drenching with phenic acid and a rubbing down of the walls with quicklime. In the treatment of diphtheria, antitoxin is always used. They have it in three strengths, and commence their treatment with the weakest serum, repeating every three hours and gradually increase the strength until they get an effect. As soon as the patient enters the hospital, a culture is taken. If the case be a favorable one, another examination is made a few days after. If, after the clinical symptoms have disappeared, a negative culture be obtained, the patient is kept for about eight days. If another negative culture be obtained at the end of that time, a transferral to the convalescent ward takes place. A discharge from this latter place is expected in ten days more, provided there be no relapse. Scarlatina takes a malignant form and is much dreaded. Special precautions are taken in its treatment and the general tendency is toward recovery, unless there be an ensuing nephritis. In order to guard against all danger, patients are kept for forty days after desquamation has ceased.

Unfortunately, my time was so limited that I was unable to enter into any investigations as to plumbing regulations. These to me, however, form a most important part of public health work in our large American cities. Mayor Quincy partially recognized this fact last year, when he

appointed a sanitary commission to examine into the condition of our public schools. And no one, who read the very excellent report of this commission, could doubt the wisdom of its appointment, or the practical science of its members. I find, by a recent number of the *New York Herald*, that that paper is following along the same line in its own city. An editorial (December 26, 1896) says:

"The inquiry which the *Herald* has been making through the aid of plumbers, physicians and sanitarians begins to reveal the immense importance and practicability of making a new departure in city hygiene."

Our people do not sufficiently realize the great change which has taken place in the conditions of life in our cities, during the last twenty years. The character of our immigrants has completely changed. A few years ago our incoming population consisted of English-speaking people, with an admixture of Germans and some French. As soon as they reached this country, they either entered domestic service, or joined foreign-born friends, who had already acquired the rights of citizenship. They thus became rapidly fused into the homogeneous mass. Now, however, we have in every city its distinct "quarters," Chinese, Armenians, Italians, Portugese and Poles herded by themselves, and limit themselves to an area of a few squares. This herding means a great increase in tenement-house living. A few years ago, also, there was great demand for small houses in the suburbs; to-day, even in those very suburbs, apartment-houses are springing up in every direction. Practically, another form of tenement-house living. Again, an excess of population in certain districts necessarily causes an overcrowding of the public schools. This overcrowding causes two evils: First, an assigning to the rooms in the schools already existing, more scholars than they can properly accommodate, and, secondly, the hiring of outside rooms which are totally unfitted for the purpose.

All these things (and many more, had I the space to detail them) prove the necessity of the supervision of a practical sanitary engineer. A thoroughly-grounded sanitarian is as necessary to-day on the boards of health of our large cities as a physician. And it is not sufficient that such a man should be a subordinate. No professional man, hampered by superiors, who have not his special knowledge, can do himself full credit. He should have, to be effective, an equal voice in all deliberations of the board, and an equal vote in all its decisions and regulations.

As far as the efficacy of the sanitary regulations enforced in Rome is concerned, some progress has already been noted. Scarlatina has diminished in its number of cases, and its mortality. As in all other cities, since the advent of bacteriological examinations, the number of cases of diphtheria reported is as great, but the mortality is much decreased. Cholera and variola, as I have before stated, no longer exist. Tuberculosis, though never the dread enemy that it is with us, has been sensibly and favorably affected.

Why not, then, try in our own city some of the measures that have been successful in other places? Two objections might be encountered: the lack of money and the opposition of the people. As for the first, there is no way in which money can be so well used by a municipality as in securing the health of its citizens. The principal opposition would be on the part of tenement-house landlords. They would soon discover, however, that the money needed for repairs after a disinfection, would be but trifling when compared with the loss caused by an unrented apartment. As for the disinfection and washing of the clothes of tuberculous patients, I believe that a department for such a purpose would pay for itself, and would be eagerly sought by those having such patients under their charge.

Very truly yours, WM. G. MACDONALD, M.D.

Formerly City Physician of Boston.

RÖNTGEN-RAY EXPERIMENTS. —The Prussian Government is reported to have appropriated \$12,000 for Röntgen-ray experiments during the current year.

METEOROLOGICAL RECORD

For the week ending January 23d, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 2,310; under five years of age 783; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 263, acute lung diseases 247, diphtheria and croup 85, diarrheal diseases 72, scarlet fever 19, cerebro-spinal meningitis 19, measles 14, whooping-cough 14, erysipelas 8.

From scarlet fever New York 13, Boston 3, Chicago, St. Louis and Baltimore 1 each. From cerebro-spinal meningitis New York 7, Washington 3, Providence and Worcester 2 each, St. Louis, Baltimore, Boston, Cambridge and Lynn 1 each. From measles New York 5, Chicago 2, Baltimore, Boston, Worcester, Lowell, Cambridge, Lynn and Somerville 1 each. From whooping-cough New York 4, Cleveland 3, Chicago 2, St. Louis, Balti-

more, Fall River, Lowell and Chelsea 1 each. From erysipelas New York and Chicago 2 each, St. Louis, Baltimore, Boston and Providence 1 each.

In the thirty-three greater towns of England and Wales, with an estimated population of 10,992,524, for the week ending January 10th, the death-rate was 19.2. Deaths reported, 4,055: acute diseases of the respiratory organs (London) 306, whooping-cough 90, diphtheria 77, measles 73, diarrhea 49, fever 45, scarlet fever 44.

The death-rates ranged from 9.1 in West Ham to 28.3 in Plymouth: Birmingham 22.2, Bradford 16.0, Croydon 16.4, Gateshead 22.7, Hull 18.3, Leeds 20.5, Leicester 15.9, Liverpool 25.1, London 18.0, Manchester 22.3, Newcastle-on-Tyne 17.7, Nottingham 23.3, Sheffield 20.3, Swansea 19.8.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 23, 1897, TO JANUARY 29, 1897.

MAJOR CLARENCE EWEN, surgeon, having served over thirty years in the Army, is, on his own application, by direction of the President, retired from active service this date, January 26, 1897.

Leave of absence for one month, to take effect about the first proximo, is granted CAPTAIN WILLIAM O. OWEN, assistant surgeon, Fort Bayard, N. Mex.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JANUARY 30, 1897.

C. E. RIGGS, assistant surgeon, detached from the "San Francisco" and ordered to the "Detroit."

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, February 8th, at 8 o'clock.

Dr. Charles H. Williams will read a paper entitled: "Standards of Form and Color Vision in Railway Service." Discussion by Drs. B. J. Jeffries and O. F. Wadsworth.

Dr. Howard A. Lothrop will read a paper entitled: "Empyema of the Antrum of Highmore, a New Operation for the Cure of Obstinate Cases." Discussion by Drs. J. W. Farlow, A. Coolidge, Jr., J. P. Clark and F. C. Cobb.

JAMES G. MUMFORD, M.D., *Secretary*, 197 Beacon St.

NEW YORK STATE MEDICAL ASSOCIATION, FIFTH DISTRICT BRANCH.—The thirteenth annual meeting of the Fifth District Branch of the New York State Medical Association will be held in Brooklyn on Tuesday, May 25, 1897. All Fellows desiring to read papers will please notify

TWO CASES OF LAPAROTOMY FOR ACUTE INTUSSUSCEPTION.¹

BY J. COLLINS WARREN, M.D.

THE following reports of two cases are submitted to the Society as examples of successful treatment of this affection by opening the abdominal cavity and reducing the invagination by taxis. The medical features of the cases will be described by Drs. T. M. Rotch and C. P. Stickney, who have kindly furnished me with notes. The salient points in diagnosis, as presented to my mind, were the sudden onset of the symptoms, the presence of a tumor, and the bloody mucus which was discharged. In neither case could the tumor be felt by the rectum.

The question of laparotomy for intussusception is one which can be discussed with profit at the present time, and it is for this purpose that those two cases are reported this evening.

CASE I. (Seen with Drs. Reid and Rotch.) F. C., male, six years old. General health good. Was attacked at 7 A. M., April 11, 1896, with severe abdominal pain, coming on every five or ten minutes, and accompanied by small movements from the bowels, at first fecal in character, but later of clear blood. A dose of medicine given by his mother was followed by excessive vomiting. The movements later contained blood-stained mucus. The extremities were cold. The pulse was slow. The temperature at 4 P. M. was 97° F. There was much prostration.

The attacks of pain and the movements from the bowels lessened in frequency in the afternoon, and there was no vomiting after 1 P. M. The pulse, which was 60 and intermittent when taken by Dr. Reid at 4 P. M., was 84 and strong at 8.30 P. M. Dr. Reid was first able to feel a tumor in the left side of the abdomen at 4 P. M.

The tongue was slightly coated.

The boy was seen by Dr. Rotch, in consultation with Dr. Reid, at 9 P. M.

The rectal examination was negative.

The abdomen was soft and resonant, except in the left hypochondrium, where there was dullness corresponding to a hard mass, apparently the colon.

Dr. Reid's diagnosis of intussusception was confirmed by Dr. Rotch.

April 12th, at 2 A. M., laparotomy was performed, nineteen hours after the first symptoms, and an extensive invagination of the transverse colon into the descending colon was found and reduced. There was much congestion, but there were no adhesions.

The operation consisted in an incision on the median line, about five inches in length, which was subsequently joined by a transverse incision on the left side about two and one-half inches opposite the umbilicus. The tumor was readily grasped, but was with difficulty brought into view, owing to the shortening of the mesocolon. The intussusceptum being finally held by the thumb and forefinger of the left hand, gentle traction was made upon the intussusciptions by the right hand which enveloped the tumor. By alternate traction and compression the intussusceptum was gradually delivered, and found to be in the condition above mentioned. The bowel was replaced

and the peritoneum was carefully stitched with catgut. The divided rectus muscle was also sewed separately. The skin and linea alba were then approximated by silk sutures. The patient bore the operation well. Convalescence took place without any accident of special interest, the wound healing by first intention. The patient has been well since and has worn an abdominal supporter with a pad made to fit the wound.

CASE II. (Seen with Drs. Stickney and Rotch.) S. S., age nine months, male. Until present attack always well. Always nursed.

First seen by Dr. Stickney May 22, 1896. Irritable in the morning and vomited the breast-milk at noon. Following this had a semi-solid movement of the bowels, with a small quantity of bloody mucus. In the afternoon restless, and had sharp, short attacks of abdominal pain, drawing up his legs. At 8 P. M., had a large, watery movement, with considerable blood and mucus; and during the night the pain and restlessness continued every quarter- or half hour, lasting about one minute. It would roll and writhe about, and beads of perspiration would stand out on forehead and face. Between the attacks it seemed exhausted.

May 23d. The watery movements with blood and mucus continued. Quieter than on previous day, and remained so until late in the afternoon. The physical examination was negative until about 6 P. M., when a distinct tumor could be felt to the left and a little above the umbilicus. The tumor was somewhat larger than a large olive, and slightly tender. Rectal examination negative. Diagnosis, intussusception.

The case was seen by Dr. Rotch, in consultation with Dr. Stickney, on the evening of May 23d. Temperature on May 22d, P. M., 100° F.; May 23d, A. M., 100.5° F. Pulse 130, good strength, regular; respiration slightly accelerated. Tumor distinctly felt in left side of abdomen, but not by rectum. Dr. Stickney's diagnosis confirmed.

May 24th. One A. M. Laparotomy about forty hours after first symptom.

An incision, almost four inches in length, was made on the median line, starting from above the umbilicus and skirting around its left margin. The hand introduced into the abdominal cavity easily grasped the tumor in the left hypochondrium. It was gradually drawn forward and brought into view. The intestines appeared to be in good condition and there were no adhesions. The invagination appeared to be at the junction of the transverse and descending colon. The tumor thus found appeared to be about six inches in length. Reduction was effected in the following manner: The right hand grasped the intussusciptions, the little finger overlapping and exerting compression upon the apex of the intussusceptum. The neck of the intussusceptum was held firmly between the thumb and forefinger of the left hand and the intussusciptions was gently pulled upon by the right hand, which at the same time exerted light compression upon its contents so as to push them out. After a few minutes' manipulation of this sort, as the bowel did not unfold, the finger was introduced and swept around the ring, through which the bowel entered the invagination, so as slightly to compress it and reduce the swelling at the outlet. After further taxis the bowel gradually unrolled itself. At no time was any traction made upon the intussusceptum. The loop of bowel, which appeared to be uninjured, the only change apparent, being a slight thickening of the mesentery, was re-

¹ Read before the Boston Society for Medical Improvement, November 2, 1896.

turned to its normal position, and the abdominal incision was closed. The time of the operation did not exceed thirty minutes, and was probably somewhat less than that. A laparotomy dressing was applied.

The bowels were moved on the second day after the operation. The temperature did not rise above 102° F., and the stitches were all removed, and the temperature was normal on the thirteenth day after the operation.

In reporting these two successful cases, I do not wish to be considered as advocating the operation in all cases. To what extent this method should be employed, and in what class of cases the treatment by enemata should be resorted to, are points which I trust will be brought out during the discussion this evening.

ACUTE INVERSION OF THE UTERUS FOLLOWING DELIVERY OF PLACENTA.¹

ABDOMINAL SECTION, REDUCTION, RECOVERY.

BY D. J. BROWN, M.D., SPRINGFIELD, MASS.

THE case which I desire to present to your attention is one of acute inversion of the uterus.

The patient, Mrs. R., white, aged thirty-five, married, mother of five children, oldest twelve years, youngest eight days. All labors were reported as being difficult, though not instrumental. No puerperal complications had existed. Menstruation at the age of fourteen, and no trouble since. Health had been fairly good. Tuberculosis on mother's side.

Present History.—First saw the patient eight days after the delivery of her last child, and obtained the following history: Pregnancy advanced to the full term without any complications; health good during that period. Labor lasted seven and one-half hours, and was the same as all others with the exception of delivery of placenta. In this the attending physician experienced considerable difficulty, and at last resorted to great traction on the cord. Upon delivery of placenta the uterus immediately followed. This was followed with severe post-partum hemorrhage and collapse. At the time of my visit the following conditions were noted: A patient quite anemic, with loss of appetite, severe cough, papular eruption on trunk and lower extremities; temperature 103.5°, pulse 120, and of poor quality.

Examination *per vaginam* revealed a rounded, dark-colored, roughened mass, which bled very easily when touched. There was considerable discharge and some odor. An attempt under ether was made to reduce it, but it was found impossible, on account of almost complete involution of the cervix having taken place, the hemorrhage produced and the poor condition of the patient. Forceful reduction at that time would mean rupture of the uterus, on account of its spongy condition. Twenty-four hours later, and with the patient's condition improved, abdominal section was performed. The cervix was dilated, pressure and internal counter-pressure were applied, and after twenty-three minutes the uterus was returned to its normal position without injury to it or surrounding parts. A stout silk suture was then passed through the uterus, brought out through the muscular layer of the abdominal wall and ligated. The wound was then closed with deep and superficial sutures, dressings and bandage applied.

Next the uterus was thoroughly curetted, irrigated with bichloride solution (1 to 2,000), and packed with sterilized gauze drain.

After-Treatment.—During the first twenty-four hours, patient was given nitroglycerin, gr. $\frac{1}{100}$, and strychn. sulph., gr. $\frac{1}{20}$, every three hours; the total amount of brandy in twenty-four hours, eight ounces. At the end of twenty-four hours gauze drain was removed, and intra-uterine douches, bichloride (1 to 2,000) given once in four hours; catheterized once in six hours.

Second day. Calomel (five doses, one grain each) was given every hour, followed by magnesia sulph., one drachm every hour, until decided results were obtained. Brandy and strychn. sulph. still continued (brandy increased to twelve ounces). Beef extract and milk with lime-water. Quinine sulph., two grains every four hours. Still catheterized. Cough troublesome, odor very slight. Morning temperature 100.5°, pulse 100; evening temperature 104°, pulse 120.

Third day. Bowels moved quite freely. Stimulants and nourishment practically the same. Morning temperature 100.3°, pulse 108; evening temperature 103.2°, pulse 120. Coughed less during the night. Catheterization stopped.

Fourth day. Morning temperature 99.5°, pulse 80; evening temperature 101.5°, pulse 102. Douche still continued, odor ceased, discharge diminished. Brandy diminished by four ounces.

Fifth day. Evening temperature 100.2°, pulse 94. Diet, egg-nogg with whiskey, one-half ounce every two hours. White of egg with lemon-juice. Beef-juice, one and one-half ounces three times daily. Strychnia, gr. $\frac{1}{20}$, still continued. Bowels still moved quite freely.

Sixth to ninth day. Improvement gradual. Brandy now diminished to four ounces in twenty-four hours. Elix. calisayæ, ferri et strychn. was now given, one drachm three times daily. Diet increased.

Tenth day. Deep sutures removed. Improvement continued.

Twelfth day. Morning temperature 98.4°, pulse 80; evening temperature 99°, pulse 88. Superficial sutures removed. Wound well healed, rash almost entirely disappeared, patient's condition very good. From this time on recovery uninterrupted.

ETIOLOGY.

"As regards the etiology of this accident, Buchler considers its chief factors are the relaxation of the walls of the uterus, the enlargement of its cavity, and a power which, acting upon the uterus, either from without or within, forces the uterus downwards." This becomes evident when it is noted that the accident almost always occurs immediately after the expulsion of the child and during the delivery of the placenta, through forcible attempts to deliver the latter, either by forcing down the fundus or by pulling upon the cord, especially when it is unusually short. The latter was the cause in the case under discussion.

Prof. Barton Cooke Hirst has had experience in three cases. He thinks it almost invariably caused by traction upon the cord or by the manual removal of the placenta. In one of his cases the womb was turned inside out by the suction of his hand, with the placenta grasped in it. He had loosened it from the uterine wall to which it was adherent, and he states that up to this time the walls of the uterus were in

¹ Read before the Hampden Medical Society, October 20, 1896.

their normal position; but directly after he withdrew his hand, he found the womb completely inside out.

Inversion may also occur when the walls of the uterus are released. Rokitansky has called attention to the fact that inversion often begins at the placental site.

When flaccidity of the uterus is extreme, a strong pressure of the intestines may produce inversion. Denucé thinks when the uterus is contracted an increased intra-abdominal pressure can cause inversion. Buchler denies this, and cites the theory of Bradford and Tyler Smith who found the cause of inversion to be activity of the inverted part with simultaneous flaccidity of the parts beneath.

This theory was rejected by Duncan and Spiegelberg, who believed that the inverted part was always passive, and that by pressure exerted upon the fundus from without, and by the intestines or by the hand forcing it down, or by dragging upon the placenta by the cord, the uterus could be inverted. When the flaccid part of the walls of the uterus is inverted, its uninverted body will be called in action and propel the uninverted parts downwards.

Thomas says: "Every influence which destroys the tone and resistance of the uterine parenchyma proves a predisposing cause of the condition." As examples, he mentions: (1) parturition, (2) distention of uterus by retained fluids, (3) distention of uterus by tumors. And among the exciting causes he mentions, (a) traction on placenta, (b) traction by polypi or tumors, (c) sudden delivery of child by traction, (d) muscular movements when relaxation exists.

DEGREES OF INVERSION.

Writers describe three degrees of inversion. In the first the fundus, or any other part of the body, is simply turned inside out, but has not yet come through the os internum. In the second the body has appeared at the os in the vagina. In the third the organ has passed the *rima vulvæ*, the inversion being then complicated with inversion of the walls of the vagina. This latter condition existed in the writer's case.

SYMPTOMS.

The chief symptoms of complete inversion occurring after delivery are discomfort about the vulvæ, faintness, nervous disturbance, hemorrhage and collapse.

Should no diagnosis be made at the time of the accident, and the case drag along until the condition becomes chronic, the following symptoms will manifest themselves:

- (1) Occasional or constant hemorrhage.
- (2) Dragging pains in back and loins.
- (3) Difficulty in locomotion.
- (4) Difficulty in defecation and micturition.
- (5) Anemia and its accompanying evils.

DIAGNOSIS.

The diagnosis of recent puerperal inversion is very easy, especially when the placenta remains attached. However, cases have been reported in which the inverted mass was mistaken for the head of another child, for the placenta, or for a polypus. Between this latter complication and inversion, the following are diagnostic points:

(1) The circular, not lateral, implantation of the pedicle.

(2) The opening of the tubes upon the inferior portion of the tumor.

(3) The special sensibility, sometimes accompanied by special contractility, that it offers to pressure and to acupuncture.

(4) The half reduction which can always be made in inversions, never in polypi.

(5) The absence of the uterus from its ordinary place, ascertained by rectal and vesical examinations.

In the writer's case, two of these conditions were absent, namely, sensibility and contractility.

If it be fibroid, the probe will show increase of uterine cavity; it will have come on gradually; it will have no reference to parturition.

PROGNOSIS.

According to Crosse, one-third of the women with puerperal inversion of the uterus die either immediately or within a month. Such a mortality undoubtedly stamps inversion of the uterus as one of the gravest accidents of labor. In 72 of the 109 fatal cases collected by him, death occurred within seventy-two hours, usually within half an hour. Crampton, in 1885, collected 120 cases. There were 89 recoveries, 32 deaths, and one remained unrelieved. Winckles states that in 54 recent cases only 12 died.

MODES OF DEATH.

Death may occur from shock or from hemorrhage. It may also occur from incarceration of a loop of the intestines in the inverted uterus, from peritonitis, from puerperal infection, or from gangrenous inflammation of the uterus. In very rare instances recovery has followed the separation by sloughing of this organ, and spontaneous restoration has taken place. Ten such cases have been recorded.

TREATMENT.

Prophylaxis is of primary importance. Let the recumbent position be insisted upon during delivery. If you recognize brevity of the cord, promptly divide it. In delivering the placenta, make no traction upon the cord, unless it be during a pain. Again, in expelling placenta endeavor to have pressure equal on all sides.

After inversion takes place, and should placenta be attached, all operators now agree that before attempting reduction the placenta should be detached.

In regard to controlling the hemorrhage, many remedies are advocated; among others alum, tannin and persulphate of iron. The writer would suggest packing the vagina firmly with sterilized gauze.

Reduction should be attempted as soon as possible, especially before contraction of the os and swelling of the fundus takes place. When reposition is impossible and the condition of the patient becomes unfavorable, reduction after the manner suggested by Thomas, together with ventrofixation seems to me the most favorable. Should this method be found impossible, nothing is left but amputation.

PLAGUE AND PROTECTIVE SERUM INJECTIONS. — Professor Haffkine is reported to have produced an attenuated plague virus which is credited with being protective against the disease. No details have yet been published respecting the methods he employs.

AN ACUTE SYPHILITIC AFFECTION OF THE EAR.¹

BY E. A. CROCKETT, M.D.

VERY little attention is paid to the syphilitic affections by any of the recent text-books on the ear, and such space as is devoted to the subject is given to the consideration of the skin lesions or the chronic bone lesions about the stapes or in the labyrinth. The general consensus of opinion seems to be that aural manifestations of this disease are rare, and relatively unimportant. This is, I am sure, a mistaken idea, for I readily found some 15 or 20 cases of this particular lesion, of which I am to speak, in about a year after my attention had been specially directed to the search for them. I do not doubt that every clinic contains many unrecognized cases of various phases of otitic syphilis, some of which endanger the other patients in the clinic.

Concerning the particular lesion of which I am to speak to-night, almost nothing is to be found in aural literature, although the significance of the group of symptoms has been recognized for a long time. I may best define these symptoms by giving one or two histories:

CASE 1. A man forty years old, with no previous ear trouble, had syphilis about six months ago. He had never received any treatment, but has had no symptoms since the disappearance of the skin eruption some three months ago. Three weeks before I saw him, he began to have ringing in the ears, which gradually increased in severity until it became very loud; at the same time a deafness began, which in the course of a week became practically complete. At the same time he had a slight vertigo so that the gait was somewhat unsteady in walking. When I first saw him, three weeks after this, his deafness was practically complete, the hearing tests being

Watch: right, $\frac{c}{60}=0$; left, $\frac{c}{60}=0$.

Voice: right, $\frac{1}{35}$; left, $\frac{1}{15}$.

Tuning-fork C, 512 v. s.: right, $\frac{8''}{b.c.}$; left, $\frac{10''}{b.c.}$.

Upper Limit: right, Galton 2.9; left, Galton 2.6.

Lower Limit, 64 v. s.: heard with both ears.

The tinnitus and vertigo, were at this time very marked.

CASE II presents some points of difference. G. E., twenty-eight years old, had syphilis three years ago, and received treatment for a year, since which time, having no further symptoms of the disease, he took no medicine. Five weeks before I saw him he had a severe cold in the head, which went away very suddenly, leaving him totally deaf. The onset of this deafness was exceedingly acute; he went to bed with his ear feeling "stuffy," and woke up absolutely deaf, and with severe vertigo and vomiting. In the next five weeks he took treatment with his family physician, without improvement. He remained very deaf; his vertigo was so severe that, to use his own expression, he was afraid to walk alone for fear of being arrested for drunkenness. He had at all times a sound like a sea-shell in his ears, and at times a clear ringing sound. At the time I saw him he staggered perceptibly to the left in walking; but a careful examination failed to reveal any other trouble than that of the auditory nerve. Both membrane tympani were clear and transparent and in normal position. The hearing test was

Watch: right, $\frac{c}{60}=0$; left, $\frac{c}{60}=0$.

Voice: right, $\frac{2}{35}$; left, 0.

Tuning-fork C: right, $\frac{10''}{b.c.}$; left, $\frac{9''}{b.c.}$.

Weber Test: fork heard in right ear.

Unfortunately no test of the upper and lower tone limits was made in this case.

CASE III. A man thirty-five years old, had syphilis six months ago, and had been under careful treatment from the time of the initial lesion. The skin eruption and other secondary lesions had been very slight indeed. Ten days before I saw him, he had begun to notice difficulty in hearing, which rapidly increased, accompanied by violent vertigo and tinnitus, until in the course of two or three days he became so deaf that he was unable to carry on his business. At this time he was taking iodide and mercury in full doses. On examination, no trouble with any other part of the nervous system was discovered, the drum membrane was clear, transparent, and in normal position. His chief complaint was of dizziness and a very loud tinnitus. The hearing test was

Watch: right, $\frac{c}{60}=0$; left, $\frac{c}{60}=0$.

Voice: right, $\frac{1}{35}$; left, $\frac{1}{15}$.

Tuning-fork A: right, $\frac{10''}{b.c.}$; left, $\frac{10''}{b.c.}$.

Galton: upper register lost in both ears; lower register 64 v. s., not heard in either ear.

As will be very easily seen, these three cases present a marked similarity of symptoms — very sudden and severe deafness, more or less severe vertigo, and violent tinnitus, occurring in persons previously free from ear trouble. This complex of symptoms should always suggest syphilis, and will be found to be caused by it in the large majority of cases where there has been no previous ear trouble. We do meet the same group in the rare cases of labyrinthine hemorrhage or tumor, and also in the rare sudden fixations of the stapes which occur in the deep middle-ear thickenings. In these cases the history and hearing tests, or in case these fail, the treatment will immediately show us the probable cause.

In this differentiation the test of hearing is especially important. It will be noticed that in all the cases I have quoted, the watch and voice deafness was very marked, and a tuning-fork of the middle register was wholly lost to bone conduction, but remained fair for air conduction. At the same time the upper register as shown on the Galton whistle was more or less diminished, and the lower limit usually remained unaltered. This hearing test is in my experience quite characteristic. On the other hand, a stapes fixation from extension would show a very marked loss of low tones, often as high as 2,000 vibrations a second where the process had extended into the labyrinth sufficiently to involve the upper register. Such a loss of low tones I have never seen in an acute syphilitic process. The acute labyrinthine processes on the other hand, show a marked loss of high tones in all cases, and in the more severe ones a total deafness by both air and bone conduction over a greater part of the register.

The pathological process in these cases is not well understood, as an opportunity for post-mortem investigation is never obtained in the acute form of the disease. In the old syphilitic process we find most commonly periosteal changes about the base-plate of the stapes and that portion of the cochlea in its vicinity, and degenerative tissue changes in the nerve-cells and blood-vessels of the cochlea.

¹ Read before the Boston Society for Medical Improvement, November 2, 1896.

The clinical evidence would seem to be in favor of an effusion into the labyrinth as a cause of the particular group of symptoms we are considering.

The early tertiary or late secondary period seems to be the favorite time for this particular lesion, although some cases are reported as early as the fourteenth day of the disease. In all of the cases I have observed, the first symptoms of the involvement of the auditory apparatus have been from three months to five years after the original infection. In some twenty cases I have never seen one earlier than three months. One case occurred in the course of hereditary syphilis in a child of eight years. Some points in the differential diagnosis are of importance. The majority of the cases that I have seen have had a diagnosis of cranial trouble made, and had consequently been given a bad prognosis; this mistake is not an unnatural one from the fact that, in the mind of the average practitioner, even a high grade of deafness is considered relatively unimportant, and the chief attention is given to the symptom, vertigo. This vertigo and its accompanying nausea is frequently quite severe. In extreme cases, the patient may be confined to his bed for several days, unable to raise his head without vertigo and vomiting; occasionally he will say that he sees double, and even in the less severe forms the patient will stagger perceptibly in walking. There should, however, be no difficulty in establishing the absence of any other cranial lesion, as a careful examination will fail to reveal the implication of any other nerve than the auditory.

As will be observed in two of the three cases quoted, this complication of syphilis frequently comes on in cases that have received careful and thorough treatment; this was especially so in Case III, who had very thorough treatment under a member of this Society from the very start of the disease. Under these circumstances the administration of mercury and iodide to the maximum limit will often be of no avail. Here the subcutaneous administration of pilocarpine up to its full physiological limit will be of great service.

The improvement in hearing and the diminution of vertigo following the administration of this drug is in acute cases little short of marvellous; for example, Case II, when I first saw him, was so dizzy that he was unable to walk to and from his place of business, and his hearing was reduced to zero in one ear, and whispered voice at two twenty-fifths in the other. One injection of pilocarpine (one-sixth of a grain) raised his hearing to ten twenty-fifths, three injections to normal; and at the end of a week, having been given in addition iodide of potassium, he was free enough from vertigo to return to work, which he had not been able to do before for three weeks.

Case III had, in addition to his regular treatment, five or six injections of pilocarpine, which raised his hearing for both tuning-fork and voice to normal, where it now, after the lapse of two years, still remains. The pilocarpine in Case II was continued over the space of two weeks, when his hearing in one ear was normal; the other ear did not respond to treatment. This was about four years ago; he continued treatment with iodide of potassium for about six months, and his hearing at that time was still good in the better ear. Since that time he has neglected treatment both for his ear and for his systemic syphilis; and in a letter received from him some months ago I

was informed that he was practically totally deaf and much troubled with vertigo.

From a fairly large experience in the administration of pilocarpine in these cases I think we may safely conclude that the drug is an absolute specific in all acute syphilitic cases presenting this complex of symptoms; that where the deafness and vertigo have persisted for over a month, the prognosis is very doubtful; that it is of great value in cases where iodide and mercury are of little avail; but that it has no permanent value, and should be used in conjunction with other syphilitic treatment. In neglected cases where the pilocarpine may have failed to improve the hearing to any appreciable extent, it will almost never fail to relieve the accompanying vertigo.

There is nothing especially new about the pilocarpine treatment; but it certainly is a very valuable drug, and its use has been curiously neglected. I have for two or three years used it as a routine treatment in all cases of progressive deafness and obstinate vertigo and tinnitus which I have seen in my service at the Eye and Ear Infirmary; but although very favorable reports by eminent aural authorities on the use of this drug in other than syphilitic cases have been published from time to time, I have, in over a hundred administrations of the drug, never seen a favorable result follow its use in a non-syphilitic case.

STERCORAL ULCER.¹

BY J. G. MUMFORD, M.D., BOSTON.

THE bibliography of stercoral ulcers is scant. Many standard authors do not so much as give it a name. Having had a few cases with similar symptoms suggesting this condition, I have been led to think that this class of phenomena has a greater importance than is credited to it by others.

Of the cases I have observed I shall detail but one, however, which is the most striking and interesting.

Doubtless in recent years, the stercoral ulcer which eventuates in what we call appendicitis has absorbed attention to the exclusion of much else, but that these ulcers are found elsewhere in the intestine there is abundant evidence.

As is now generally recognized, the presence of an impacted fecal mass is the commonest and important causative factor in appendicitis, the usual sequelæ being localized enteritis, swelling, malnutrition, necrosis, ulceration, perforation.

The older medical writers, while failing to recognize the great frequency of these processes in the appendix, did mention them as occasionally occurring in other portions of the intestines, notably at the flexures of the colon, the caecum, and the rectum, and referred them to that unusual and rather mysterious disease "mucous colitis," or to chronic constipation. I doubt the importance of the former, but am convinced that a chronic constipation, especially when complicated with a long-continued local impaction, may and does give rise to ulcerations more frequently than the pathologists tell.

Naturally, when impactions, inflammations, necrotic patches and ulcerations in the course of the large intestine do not lie in the cul-de-sac appendix, they often do not result seriously.

¹ Read before the Warren Club, December 1, 1896.

However, that an extensive conflagration may start from such a focus is evident from the following case:

Mr. F. M., about forty-five years of age, has been under my care for a year. His general health has been only fair, though he is a vigorous, well-developed and active man, mentally and physically.

He has been for some ten years subject to occasional attacks of epigastric pain, which sometimes have required up to three-fourths of a grain of morphia to quiet them. A free use of salines has put a limit to each attack, in one of which only had I attended him previous to the illness to be described. He had never been a hard drinker or smoker, though he has been subjected to the ordinary American boarding-house diet. For the past year he has lived in Nahant, and has indulged moderately in the abominable drinking-water of that region.

On the 17th of last August I was called to see him in the afternoon. He was in bed, writhing with pain referred to the epigastrium. His bowels had operated that morning, but he had had much malaise for upwards of two months, owing, he thought, to sluggishness of peristalsis.

His temperature was 100° F., pulse 80. Abdomen soft, face anxious, tongue furred. A doughy mass could be felt, presumably in the transverse colon. This was very tender on palpation. Elsewhere the abdomen was soft and free from pain. I quieted him with a hypodermic of morphia, and ordered an ounce of castor oil, to be repeated in twelve hours. He passed a restless night. The next morning he was still very restless, but somewhat more comfortable; the abdomen was slightly distended.

He had had two enormous solid evacuations of the bowels—"Pounds," his nurse said. With these, however, his general condition did not at once improve, as I had anticipated. The urine was scanty, high, specific gravity 1.036, loaded with albumin and casts.

On the third day there was a change for the worse. Exquisite spasmodic pain in the perineum and the passage of blood were complained of.

There were three or four stools daily, of a gruel-like consistency and muco-purulent character. Small shreds of tissue could be seen in them.

An examination of the lower rectum showed a small hemorrhoid, with the neighboring mucous membrane velvety and intensely congested. Abdominal palpation had become very painful. The knees were drawn up. There was greatest tenderness over the course of the transverse and descending colon.

The face was anxious and the tongue thickly coated with black fur. Enormous eructations of gas were frequent, and there was absolute anorexia. Flatus passed freely; but there was no diminution of the distention. In other words, we had here a marked, acute gastro-enteritis, with possibly a mild peritonitis, and an acute nephritis. The temperature ran along at about 100°, with a fairly steady pulse.

All this went on with but little change till the seventh day. On that day I found the following conditions: Decubitus the same; great restlessness; abdomen enormously distended and tympanitic. In some considerable experience with abdominal surgery, I have never seen such distention. It seemed as though he would burst if touched. The greatest tenderness was still in the region of the splenic flexure; and at this place there was an area nearly as large as one's

palm, of great pain. If possible the distention at this place was more pronounced than elsewhere.

The face was haggard, the mind confused. Vomiting came on in the morning and towards night the character of the vomitus became fecal. At 6 p. m. he regurgitated freely the contents of the jejunum.

In twenty-four hours he had passed twenty ounces of high-colored urine; in which I roughly estimated over two per cent. of albumin. The specific gravity was 1.038, and there were innumerable casts with free blood. The temperature had reached 101° F. The patient would have been pronounced *in extremis* by any tyro.

My only hope clung to a full regular pulse of 90. This was at 6 p. m. Two hours later the pulse became more rapid and irregular—100 to 120. The patient was in mild delirium, and sinking fast. I told the nurse to give him a large hypodermic of morphia—one-half a grain, for he stood large doses—and to make his last moments as comfortable as possible.

I made a midnight visit. He was asleep. There had been no more vomiting. The pulse was steady at 100.

From that time on he began to improve. The stomach began to take care of food, the pain to diminish, the urine to clear up, and the temperature to come down.

The convalescence was rather slow. He had several slight relapses, and the abdominal distention was apparent after four weeks. However, he got well and is now in Europe.

I have described these symptoms in some detail, because the diagnosis was for a time obscure and the course unusual.

Of the initial fecal impaction there was evidence enough. The doughy mass first felt disappeared with the enormous dejections, but the enteritis and gastritis quickly supervened. The presumption is that the onward movement of the foul fecal masses over a sensitive mucous membrane accounts for the implantation of pathogenic bacteria in numbers sufficient to cause a rapidly spreading inflammation. Then, too, a stercoral ulcer at the seat of impaction undoubtedly existed and served as a nidus for fresh infection. It is a well-ascertained fact that such ulcerations are the result of a long-continued irritating impaction. The rapid spread of the inflammation was doubtless due to the man's lowered general condition.

I have said that there was a gastritis also present, and I base my belief in that on the fact that the stomach itself was distended and that the eructations of gas were enormous after the third day. At the same time flatus and feces passed *per anum* until the day of fecal vomiting. The whole course up to that day is certainly not very suggestive of a peritonitis.

Fortunately, there was no autopsy to confirm the diagnosis, but the onset of acute pain in the region of the splenic flexure, the subsequent increased distention, obstipation, and fecal vomiting leave one no other conclusion than that there had been a perforation and a localized peritonitis on that day.

Then there came the usual symptoms of approaching death and the large hypodermic for the relief of pain.

I admit that I had in mind the thought of checking peristalsis by morphia, and possibly assisting self-limitation of the peritonitis; but with almost no hope. From the result I believe the drug saved the man's life.

The question naturally arises, Why did I not do an immediate abdominal section? Because when the evidence of perforation was established the patient was obviously dying, and I was alone in the country, at least two hours from assistance. Ether would certainly have killed him.

There is in all this a curious analogy with the development of an acute appendicitis, but with the important distinction that the peritoneum is not so immediately threatened as in the case of an ulcerative appendicitis.

In the latter case necrosis and perforation into the peritoneal cavity are often rapid and fatal, but, *a priori*, it seems probable that an ulcer of the colon would be so slow in perforating as to give more time for a circumscribing peritonitis.

Certain it is that in my case peritonitis was limited in extent and quickly subsided. The etiology of the condition in this case is interesting. Let me premise this by saying that, in sixteen months, I have seen in Nahant seven cases of fecal impaction and a very unusual number of cases of obstinate constipation, especially in children. I have come to feel that the town water of the region — known as "Marblehead water" — is largely at fault. The exact analysis I cannot give, but it contains a very large proportion of lime salts in solution. It is so "hard," as the term is, that only the boldest can successfully bathe or shave with it.

It has become my routine practice to forbid the drinking of it by children. With this conviction about it in mind, I was much interested the other day to read in the *Lancet* a passage from an article by Lauder Brunton, in which he attributes much constipation to the improper quality of drinking-water as well as to its improper quantity; and he deprecates the use of water from a chalky soil, such water being very conducive to constipation.

In the treatment of this and similar cases it is better to use salines with plenty of water rather than oil or drastic cathartics.

I have usually done so, as the intestinal contents are thus very largely diluted and irritation of the gut is less. Frequently repeated doses of salts in plenty of water has been my rule. In this case I gave oil disguised in paregoric, as the patient was in great pain and I wanted to obtain as soon as possible the soothing influence of that excellent combination. Throughout the course of the disease the further treatment consisted of salol, lithia, milk and champagne, with morphia as indicated.

Clinical Department.

ABDOMINAL HYSTERECTOMY COMPLICATED WITH DOUBLE OVARIOTOMY: RECOVERY.

BY O. J. PFEIFFER, M.D.,
Surgeon to St. Luke's Hospital, Denver, Col.

MY patient Miss —, age between thirty and forty, came to me for examination in May, 1896. She had been examined by me in the spring of 1893, at which time she was (examination without ether) supposed to have three small fibroid tumors of the uterus. Examination now revealed one large tumor, the size of a football, solid to the touch, and a second smaller one, the size of the fist, in front of and

below the first. Both seemed closely adherent to each other, firm on manipulation, and moved with the uterus as one mass. I supposed two of the fibroids found three years before had gone on enlarging, and had obscured the third.

The patient was operated upon at St. Luke's Hospital, Denver, in June, 1896, Dr. E. J. A. Rogers, of Denver, assisting. The patient was in the Trendelenburg position. An incision was made from above the umbilicus to the pubes, and the large tumor on coming into view proved to be an ovarian cyst. In passing the hand around the cyst, to see if adhesions existed, it was ruptured at its pedicle, and a brownish fluid with black flakes escaped into the abdominal cavity. This was rapidly flushed out with sterilized water; and an incision in the collapsing cyst wall drained off the remaining fluid over the edge of the abdominal incision, the cyst wall being drawn up to overhang the abdominal wall. The cyst was freed of adhesions by dissecting off with the thumb-nail about nine inches of small intestine, after which the pedicle could be secured in the usual manner and the cyst wall cut off.

The right side furnished a slightly adhering and easily detached ovarian cyst the size of a very large kidney, which had a pedicle easily ligated and divided. The uterus had attached to its fundus a fibroid tumor the size of a fist, and it was amputated at the level of the internal os in the manner originated by Dr. John Homans, and so clearly described by him in the *Boston Medical and Surgical Journal*.¹ The broad ligaments were tied off as low as possible with two ligatures on each side, one inch apart, care being taken to avoid the bladder; and the broad ligament was divided on both sides between the ligatures; then peritoneal flaps before and behind were made and reflected back. The uterine arteries were ligated by the aid of an aneurism needle; the uterus was divided by a V-shaped cut, forming anterior and posterior uterine flaps, which were sewed together; and the peritoneal flaps were brought together over the stump.

The abdominal cavity was flushed out; the incision was sewed up; gauze and rubber-tube were used for drainage, extending from the fossa of Douglas to the lower end of the incision.

A hand-to-hand fight with shock followed for twenty-four hours in which figured brandy, strychnia, digitalis, nitroglycerine and oxygen, after which the patient rallied and made a steady and complete recovery. The drainage was gradually removed, and the patient was up in four weeks, and in six weeks went East for the summer.

November, 1896. Patient has since returned to Denver, has gained twenty pounds, and is in perfect health.

RESTRICTION OF THE MECCAN PILGRIMAGE.—All the European Governments are thoroughly aroused to the danger of infection, and the powers ruling Mohammedan subjects are placing restrictions upon the pilgrimage to Mecca. The movement of the French subjects in Northern Africa is just now a matter of French legislation, and the Mohammedans in Eastern Europe — in Albania, in Herzegovina, etc. — are being told that restrictions are to be placed upon their intended visit to Mecca. The Indian Government has closed its infected ports to the departure of pilgrims.

Medical Progress.

RECENT PROGRESS IN OBSTETRICS.

BY CHARLES W. TOWNSEND, M.D., BOSTON.

THE TREATMENT OF ECLAMPSIA.

THE International Congress of Gynecology at Geneva¹ discussed the treatment of eclampsia on September 2, 1896.

N. Charles, of Lüttich, after considering the complex character of the affection, stated that he had found in 151 cases a maternal mortality of 24.42 per cent., and one of 41.83 among the children.

Charpentier, of Paris, urged the great importance of careful examination of the urine in pregnant women and in all cases of diminished urine, edema or albuminuria, he would insist on a strict milk diet. If the patient be robust and cyanotic, he would bleed in the presence of eclampsia, and give chloral and milk through a stomach-tube if necessary. Chloroform inhalation and subcutaneous injections of salt solution he also believed of value. Where the patient was not strong and not cyanotic and the eclampsia not severe, chloral treatment would be enough. *Accouchement forcé* or Cæsarian section should only be resorted to in exceptional cases. It is better to wait until the full dilatation of the cervix before completing the labor. The induction of labor should also rarely be resorted to.

Halbertsma, of Utrecht, believed that the most important question to be decided was whether the physician should terminate the pregnancy himself, or wait for nature. He thought that he ought to interfere when the attacks were severe and frequent, or the anuria absolute, or where the labor was difficult or prolonged. He believed in the incision of the cervix in difficult cases.

Veit, of Leyden, said that it was impossible to lay down exact rules for treatment, as we had not sufficient pathological basis to go on. The systematic use of large doses of morphine seemed to him the most satisfactory treatment.

Byers, of Belfast, recommended the use of morphine (thus lessening the chance of bronchial catarrh and pneumonia), elimination by hot baths, etc., and where the conditions were favorable, delivery under chloroform.

Tarnier, of Paris, spoke of the great value of milk diet in prophylaxis of eclampsia, and in all pregnant women where there was nervousness, sleeplessness or headaches. The results in his clinic from 1838 to 1887 showed a maternal mortality of 37 per cent. From 1889 to 1891 he treated the eclamptics with chloroform, chloral and blood-letting, with a mortality of 38 per cent. From 1892 to 1895 he treated the eclamptics with blood-letting, purgatives, chloroform and chloral, and especially with milk (even by stomach-tube, if necessary). The mortality was reduced to nine per cent.; and since January, 1896, no case of death from eclampsia has occurred in his clinic.

Dr. Ferre² reports in detail seven grave cases of eclampsia treated by large subcutaneous injections of salt solution. Mild cases are not included in this list, as will be seen by the fact that the patients suffered

from 11 to 40 complete convulsions and were in uninterrupted coma from thirteen to sixty hours. Only one patient died. The total quantity of salt solution injected varied from 1,600 to 5,640 grammes. Venesection, to 600 grammes, was also practised in these cases. Labor was normal or expedited, but not forced.

J. Clifton Edgar³ believes that in the majority of instances, if not in all, the eclamptic seizure is a preventable accident. He advocates frequent examination of the urine as to its amount, specific gravity, etc., as well as to the presence of albumin. In threatening cases, a milk diet, with eliminative treatment, should at once be instituted. When these methods fail, he believes in rapid and complete dilatation of the os, and delivery.

In the presence of an eclamptic attack he offers for combined treatment three indications:

I. *Control the convulsions.* For this he uses chloroform, veratrum viride and chloral. Morphine he has abandoned almost entirely, believing that it prolongs the post-eclamptic stupor and increases the tendency to death during coma by interfering with the eliminative processes. As regards veratrum viride, he says: (1) This drug reduces the pulse-rate, and convulsions are practically unknown with a pulse-rate of 60 or under; (2) it reduces the temperature; (3) it relaxes and renders more yielding the rigidity of the cervical rings; (4) it causes prompt diaphoresis, and (5) diuresis.

II. *Empty the uterus, under deep anesthesia, by some method that is rapid, and will cause as little injury to the woman as possible.* He believes that those who leave the uterus alone in eclampsia until the os is fully dilated, for fear of precipitating eclamptic attacks by manual dilatation, will see many cases lost that might otherwise have been saved. For the dilatation of the parturient os he recommends especially the bimanual method, which he figures, and he particularly warns against premature extraction of the fetus before full dilatation has been secured.

III. *Elimination of the poison or poisons which we presume cause the convulsions.* Catharsis by the various methods, glonoin, veratrum viride, and the hot-air bath are all used. Pilocarpine, in the presence of an eclamptic attack, he utterly rejects, because of the danger of edema of the lungs and glottis which it may produce. Oxygen, strychnine and alcohol are all of great value.

CARDIAC DISEASE COMPLICATING PREGNANCY.⁴

L. Demelin observed 64 cases of cardiac disease among 5,162 cases of labor in the service of Tarnier. These 64 women had passed through 162 pregnancies, in 107 of which there was no serious accident or symptom attributable to the heart, a percentage of 66.

The accidents that can be attributable to the heart lesions are classified as follows:

	Cases.
Dyspnea (notable or grave)	23
Bronchitis	3
Syncope	7
Edema (marked)	7
Albuminuria (cardiac)	12
Gastro-hepatic accidents	2
Epistaxis and hemoptysis	5
Uterine hemorrhages of pregnancy	9
Post-partum hemorrhages	7

¹ Centralbl. für Gynäkol., No. 39, p. 991.

² L'Obstetrique, November 15, 1896, p. 487.

³ Medical Record, December 26, 1896, p. 913.

⁴ L'Obstetrique, January 15, 1896, p. 41.

Two of the mothers died, a mortality of only three per cent. This small mortality, as compared with that given by other obstetricians, he attributes to the fact that, as a rule, the heart is not examined unless serious, often fatal, heart symptoms exist; and many mild cases of true cardiac disease go through pregnancy and childbirth unobserved.

One of the fatal cases was due to uremic accidents, the other occurred in a rachitic patient with a heart fatty degenerated.

He relates two cases where the patients became cyanotic, with much-embarrassed heart and respiratory action, yet recovered. One of these, so dangerously ill with her first parturition, passed through a second without a bad symptom.

The fatal mortality was 15 out of the 162, including 4 abortions and 11 deaths of premature infants.

The cardiac lesions were as follows:

	Cases.
Mitral insufficiency	22
Mitral stenosis	6
Double mitral	3
Aortic	2
Aortic and mitral	4
Myocarditis	2
Adhesive pericarditis	1

He draws the following therapeutic deductions:

"The mere finding of a valvular souffle is an insufficient motive for intervention. Conception, childbirth and nursing are possible and even perfectly easy among those with cardiac diseases.

"All essentially depends on two grand conditions: (1) The anatomic-physiological state of the myocardium; (2) the anatomic-physiological state of the large emunctories (liver and kidneys).

"The artificial termination of labor, even the interruption of pregnancy, are demanded in grave cases. But, when menacing accidents appear more or less far from term, and without a spontaneous tendency to the expulsion of the fetus, the following therapeutic means should be followed in turn: (1) Medical and dietetic means. (2) Bleeding, whose powerful action ought not to be misunderstood or neglected. (3) Artificial interruption of pregnancy in the gravest cases."

INDUCTION OF PREMATURE LABOR.

T. Arthur Helme⁵ describes a modification of Pelzer's method of inducing labor by the injection of glycerine. The modification consists of the injection of glycerine into the cervix instead of carrying the syringe tube up into the uterus. His conclusions are (1) that the intra-cervical injection of glycerine produces a rapid and progressive dilatation of the cervical canal; (2) that at the same time the lower pole of the ovum becomes detached from the lower uterine segment; (3) that the intra-uterine injection of glycerine between the detached portion of the membrane and the uterine wall may be carried out without fear of puncturing the membranes or of interfering with the placental attachment; and (4) that labor is effectually induced.

Helme makes repeated injections of 1½ ounces of pure glycerine.

PERIPHERAL NEURITIS IN PREGNANCY.

George Elder⁶ reports two cases of this affection confined to the arms and hands alone in one, affecting the feet also in the other. Both began about the

sixth month. There was tingling and feelings of "pins and needles," with lack of tactile sensibility. Recovery took place in one and four months respectively, after delivery.

Solowjeff and Polk have each reported a fatal case of peripheral neuritis in pregnancy. Remembering this fact, that the disease may prove fatal, one must be prepared to induce labor before the disease has advanced too far, for as soon as the uterus is emptied, there is naturally a tendency to recovery.

GANGRENE DURING THE PUERPERIUM.

Thomas Oliver⁷ reports two cases of this rare affection situated in the leg due to sudden blocking of the popliteal artery, occurring on the fourteenth day in one case, on the eleventh day in the other. In both cases amputation of the leg was required. The first case recovered; the second died of septic pneumonia and ulcerative endocarditis. In both cases there was agonizing pain, and analgesia and anesthesia of the affected limb.

E. R. Rouse⁸ reports a case where acute mania succeeded delivery. On the subsidence of this affection in the three weeks of the puerperium pain in her feet and fingers was complained of, which on examination were found to be white, cold and anesthetic. On the following morning the toes of both feet and the fingers of one hand and the right ear were in a condition of gangrene, the case simulating very closely one of Raynaud's disease. Both legs were amputated and the patient recovered.

A second case is reported by Rouse, where the patient was admitted to his asylum with acute mania three months after the birth of a child. Two weeks later her mental symptoms improved coincident with beginning gangrene of the right leg. This was amputated, and the patient recovered. An examination of the amputated leg showed venous thrombosis and endarteritis of the large arteries.

SERUM THERAPY OF PUERPERAL SEPSIS.

Barton Cooke Hirst⁹ says that although the antitoxic serum for puerperal sepsis be prepared with the greatest care, there is a possibility that it may contain dangerous toxins, and that the treatment may be more dangerous than the disease. There is a streptococcal infection so virulent that the antitoxin will be of no avail, no matter how strong it may be. There is an undeterminable time in streptococcal infections when the serum will be used too late. The anti-streptococcal serum has no antagonistic power over other pathogenic micro-organisms. It is not easy to determine during life whether the infection is pure or mixed, though the majority of puerperal infections are due to streptococci. Therefore the use of the serum must be more or less empirical. Finally, the clinical results of the serum therapy for puerperal infection have not been as yet at all encouraging.

Hirst thinks that the plan of treatment for the artificial production of hyperleucocytosis is much more promising. Hofbauer, in Vienna, reports the results of employing Horbaczewski's nuclein in seven cases of puerperal infection, with favorable results in some cases.

John D. Williams¹⁰ reports six cases of puerperal

⁷ Lancet, July 4, 1896, p. 15.

septicemia treated by the anti-streptococcic serum, together with eight others, all severe cases, which he has collected from literature. Two of these fourteen ended fatally. In ten cases the records are complete. None of these cases were injected without a previous thorough trial of the usual constitutional and local remedies. In two of the cases only were the cases proved bacteriologically to be true streptococcic infection. In every case with the exception of three, the temperature and pulse were reduced after each dose of serum in from six to twenty-four hours. Williams's own fatal case he attributes to the injection of too little serum and he cannot agree with Gaulard, who attributes his own fatal case to the injection of too much serum.

The serum comes into play when the germs have passed into the general circulation, by annulling their action and toxin and obviating the organic degenerations which are otherwise beyond our control.

Reddy,¹¹ of Montreal, reports a case of puerperal septicemia starting from an enlarged vein that had ruptured on the left labia. Streptococci and staphylococci were found in the membrane at this spot. Ten cubic centimetres of Marmorek's serum were injected with a resulting fall of temperature to normal in forty-eight hours and disappearance of the membrane. Much blood appeared in the urine and continued for several days.

BACTERIOLOGY OF VAGINAL SECRETIONS.

Barton Cooke Hirst,¹² in an article under the above title, draws the following conclusions of great interest to obstetricians:

"The vagina becomes infected almost immediately after birth. In a normal condition it contains no pathogenic bacteria. It has strong germicidal powers, which serve to guard a woman against infection. These powers depend, as far as our present knowledge goes, upon the presence of a special bacillus and upon the products of its life processes; upon the leucocytosis due to chemotactic action; upon phagocytosis; upon the germicidal powers, perhaps, of the anatomical elements of the vagina, of the cervical mucus, and of the bloody discharge during menstruation and the puerperium.

"During and after labor mechanical safeguards of the most effective kind are furnished against infection. These are the discharge of the liquor amnii, washing out the vagina; the passage of the child's body, the descent of the placenta and membranes, and the bloody discharge which follows.

"Moreover, should the vagina exceptionally contain pathogenic bacteria, they are likely to be in a condition of diminished or absent virulence, in which condition they will not be productive of disease unless the tissues with which they come in contact are reduced in vitality.

"Bearing these facts in mind, it would seem that the common practice of relying upon vaginal douching for disinfecting the vagina before labor, is faulty, not to say foolish. It has been clearly demonstrated that the injection of an antiseptic fluid into the vagina will not destroy pathogenic germs there, and will, moreover, rob the woman to a certain extent of the safeguards against infection that Nature provides for her.

"If, therefore, under certain circumstances, it is desirable to disinfect the vagina, mere douching should not be depended upon, but the vaginal mucous membrane should be thoroughly scrubbed out as well as douched, just as one would prepare the skin for an important surgical operation."

FIBROMYOMATA AND PREGNANCY.

F. W. N. Haultain,¹³ after a brief account of cases, concludes that fibromyomata of the uterus tend to cause sterility by preventing conception and tending towards abortion, should they be so placed or have attained such dimensions as to cause symptoms of their presence in the non-pregnant condition. As regards diagnosis of pregnancy, where fibroids also are present, this is often difficult, the tendency being for the pregnancy, on the one hand, by softening these growths, to change the normal "feel," while, on the other, the irregular hemorrhages, etc., due to the fibroid tend to mask the ordinary symptoms of pregnancy.

Though in a large number of instances the course of pregnancy is in no way influenced by the coexistence of fibroids, their presence considerably increases the risks of pregnancy by complicating labor in preventing ready expulsion of the ovum and predisposing to severe hemorrhage. The prognosis depends on the site and size of the tumor. Thus, when subperitoneal, unless the growth be of sufficient dimensions to cause severe pressure on surrounding organs, or is incarcerated in the true pelvis and thereby obstructs the passages, little or no inconvenience, is, as a rule, to be anticipated. Even in these cases, however, retrograde changes in the tumor, that is, suppurative and necrosis, may occasion anxious and even fatal consequences. With the interstitial and submucous varieties, the association of pregnancy must at all times be considered of grave import.

DILATATION OF THE PERINEUM IN LABOR.

Dr. G. Coromilas,¹⁴ of Greece, describes the following method by which he has been enabled to shorten labor, diminish pain, and prevent lacerations of the perineum. After proper antiseptic precautions, the *accoucheur's* hands and the perineum, vagina and os uteri are anointed with the following ointment:

Cocaine, three grammes; antipyrine, three grammes; vaseline, fifty grammes. Four fingers of one hand are then passed within the vaginal orifice, and semilunar movements are made, first on one side and then on the other, so as to dilate the perineum. After three or four such powerful movements, the fingers of the other hand are introduced and the performance repeated. When the requisite degree of dilatation is achieved, the fingers are passed into the vagina until the index, middle and ring fingers touch the os uteri, the same movements are made, the perineum being pushed outward with the palmar surface of the hand.

POST-PARTUM HEMORRHAGE.

E. Staunmore Bishop¹⁵ urges the importance of compression of the aorta as a rational and efficient means of checking post-partum hemorrhage. If this is done the hemorrhage is at once absolutely stopped, and without needless hurry the secondary measures can be employed to empty the uterus of clots to bring

¹¹ Montreal Medical Journal, September, 1896.

¹² American Journal of Obstetrics, July, 1896, p. 11.

¹⁴ Edinburgh Medical Journal, August, 1896.

¹⁵ Lancet, October 31, 1896, p. 1215.

about firm contraction. The ulnar surface of the closed hand should firmly compress the aorta against the spine, while the other hand is free to compress the uterus.

RETROVERSION OF THE PREGNANT UTERUS.

Murdoch Cameron¹⁶ believes that in the majority of cases the condition is probably due to previous displacement, but it occasionally arises acutely from a strain or a fall. Over-distention of the bladder is more frequently an effect than a cause, but once retroversion had taken place, an over-distended bladder would tend to aggravate the condition and prevent its cure.

In fatal cases death has occurred from the manipulations, or of necrosis of the tissues. The symptoms enumerated in those cases which terminated fatally were: (1) retention of urine; (2) febrile symptoms; (3) bearing-down pains at pelvic outlet, with anxiety and great restlessness; (4) delirium; (5) intermittent pulse; (6) coldness of extremities, moribund sweats and convulsions; (7) in a number of cases rupture of the bladder.

He reports a case of pregnancy of four months, where the uterus was retroverted, the bladder being enormously distended. Eighty ounces of urine were drawn off. On the next day blood appeared in the urine; and later a blood cast of the ureter, some fifteen inches in length, was withdrawn. Ten days later abdominal section was done, the bladder opened and cleared of blood-clots. When this was done, the bladder contracted, and it was possible to reach the uterus. By combined pressure from below through the vagina and traction through the abdominal wound from above the incarcerated uterus was pulled out of the pelvis. The patient made a good recovery, blood disappeared from the urine and she was delivered, at full term, of a large healthy child.

THE RELATIVE ADVANTAGES OF FORCEPS AND VERSION AS A MEANS OF EXTRACTION IN CASES OF MODERATE PELVIC DEFORMITY.

The above was a subject of discussion at the sixty-fourth annual meeting of the British Medical Association¹⁷ held last July at Carlisle.

R. Milne Murray opened the discussion by stating that forceps present obvious advantages from the point of view of the safety both of the mother and the child. Thus as to the mother, we have (1) avoidance of risk of uterine rupture, (2) avoidance of intra-uterine manipulation, (3) diminished risk of infection; and, as to the fetus, (1) avoidance of traction on the neck, (2) avoidance of compression of the cord.

In justo-minor pelves the question of turning does not arise, forceps being the only proper operation. In flat pelves version is almost universally recommended, while only recently has the accuracy of this view been questioned. Murray had already shown that the diminution in the cranial capacity produced by compression of the forceps is compensated by a vertical expansion and not by a transverse one. Accordingly he holds that the explanation of the inefficiency of the ordinary forceps in a flat pelvis is due, not to complications arising from their grasp of the head, but to waste of force arising from error in the line of traction.

He therefore urges the use of axis traction, offering for this purpose the rods devised by himself to be applied to ordinary forceps. He claims these points for axis traction in flat pelves: (1) the forceps can be applied without difficulty to the antero-posterior diameter of the head and in the transverse or roomy diameter of the pelvis; (2) the grasp of the head, while sufficient to prevent slipping, does not materially compress the head; (3) no amount of practical compression of the head in this direction is capable of causing the least expansion of the biparietal diameter; (4) the mode of grasp favors the development of the Naegale obliquity, and this follows the natural mechanism of delivery in such cases; (5) as compared with version, forceps avoid intra-uterine manipulation, traction on the neck of the child, and also the risk of delay during compression of the cord.

He has delivered living children in this manner, where the brim was not more than 3.25 inches, and in one case where it measured 2.75 inches.

C. E. Buslow agreed with Murray, except that he believed version would sometimes succeed where forceps failed.

W. E. Fothergill believed that version in flat pelves had nothing in its favor except its antiquity. He had successfully delivered by axis-traction forceps six women in whom the conjugate varied from three to three and one-half inches. A further advantage of forceps besides those mentioned by Murray is that forceps can be applied at any time, however long, after the rupture of the membranes.

Munro Kerr, Cameron and Connel were all practically in accord with the position taken by the first speaker.

WALCHER'S POSITION IN PARTURITION.

W. E. Fothergill¹⁸ finds that in about thirty cases measured by him the average increase in the diagonal conjugate gained by the Walcher position was one centimetre, the claim made by Walcher. The parturient woman is placed in the lithotomy position and the legs allowed to hang down, the feet not touching the floor. If the bed is low, pillows are placed under the buttocks so as to raise the body until the feet hang clear of the floor. There is a tendency to pull the patient off the bed, but she may be held by the anesthetist, or bands passed under the arms and fastened to the bed. He reports several cases where extraction failed until the Walcher position was adopted, when it took place without difficulty.

He sums up as follows:

A. In high-forceps cases, and after perforation the position saves (1) The strength of the operator, (2) pressure on the head, (3) pressure on the symphysis, (4) pressure on the perineum by forceps.

B. In cases of difficulty at the brim not needing forceps, and in breech cases, the position saves (1) exertion to the uterus and abdominal muscles, (2) pressure on the head, (3) pressure on the pubic symphysis.

C. In all cases, with or without forceps, where the perineum is in danger, extension of the legs at the hips is of advantage in relaxing the integument and subjacent structures at the vulvar orifice.

It is reported that Lord Lister is contemplating a visit to America during next summer.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

J. G. MUMFORD, M.D., SECRETARY.

REGULAR Meeting, Monday, November 2, 1896,
DR. C. J. BLAKE, the President, in the chair.

ORAL COMMUNICATIONS.

DR. F. S. WATSON: As one of the dissatisfactions of surgical practice is the losing sight of the ultimate results of cases after surgical operation, so a corresponding satisfaction occurs when we are able to follow them for long periods. I do not think, therefore, that I need offer any excuse for asking the attention of the Society once more to a case I reported last year and which is now thirteen months from the date of operation. And more especially as it is the only operation of the kind done in this country and was then the third that had been performed anywhere. The case was fully reported in the *Boston Medical and Surgical Journal*, April 2, 1896.

The patient is a woman who a year ago last September came to the City Hospital in a dying condition. She had had for a year very frequent vomiting; she was greatly emaciated, having lost forty pounds in weight within the past year. The stomach could retain no food and she suffered a great deal from pain in the stomach. There was a history of gastric ulcer seven years before. Upon examining her, I found a slight sensation of resistance in the epigastrium on the left side and slight rigidity of all the abdominal muscles, but no distinct tumor could be felt. I told her I might give her relief by an operation, having in mind rapid anastomosis between the stomach and intestine in case of finding cancer, but I could not promise anything in regard to saving life and I told her she might die on the table. On the following day I operated and she got the reward of her courage. I found an hour-glass constriction of the stomach due to contraction of the cicatrices of former ulcers which antedated the operation several years and of which there was a pretty clear typical history. It occurred to me on the spur of the moment, and without having any precedent to authorize me in so doing to turn the pyloric half of the stomach upon the cardiac portion—using the constriction as a hinge—to sew the two together and make a communicating hole between so that the gastric contents might pass through both halves of the stomach without going through the constriction. I did this as rapidly as possible. It also occurred to me first to sew the two portions all around before making the communication between them, and to do the latter through an incision made in the roof in the presenting part of the stomach. A single row of silk sutures was used to unite the two portions; one long suture was left at each corner of this ellipse in order that I might know where my knife was going and might not go beyond the borders of the ellipse made by the sutures. I then incised the presenting portion of the stomach and made the communicating cuts, then button-hole sutured rapidly the edges of the two coats so that they might not unite, and finally sewed up the wound in the presenting portion, and put the stomach back in the abdominal cavity.

The next morning to my surprise she was alive.

The wound healed perfectly by first intention. She had no hernia. I fed her for seven days by rectal enemata, after that by mouth with milk and champagne mixed and champagne and egg mixed. The first time she took food by the mouth I was interested to know what her sensations were, and she said it passed through without pain and without trouble. She has had no trouble practically speaking from that day to this and has continued to gain. She is now in perfect health and weighs more than at any time in her life.

PATIENT: I have no trouble from the operation at all. For three years before the operation I lived in agony all the time. I am now perfectly free from pain. When I take food I am not conscious of any thing but a perfectly natural feeling in my digestion.

DR. WATSON presented a second patient, and said: This patient is an example of the recently popularized operation of castration for the relief of prostatic hypertrophy. He came to the City Hospital, and after trying for two months the most thorough treatment to relieve his condition of chronic retention of urine from obstructive prostatic disease, cystitis, and a slowly increasing loss of vitality, I removed both testicles. He had no trouble following the operation, and has been absolutely and entirely comfortable ever since. The prostate has disappeared and is now below its normal size. Before the operation it was about as big as an average russet apple. Catheterization was very difficult. He bled profusely when it was first done.

PATIENT: I think it was a very successful operation. It has been some six or seven weeks since the operation, and I don't think I was ever better in my life.

DR. WATSON: The patient has shown no evidence of the accident which sometimes follows the operation, namely, mental derangement, which has been noticed in a certain number of cases. The statistics published recently by Dr. Cabot which seem to show that the mortality of this operation is nearly as high if not higher than from the operation of prostatectomy, were a great surprise to us; in spite of them it is hard to feel convinced that the operation of castration is as dangerous as the other.

In the most successful case of castration performed by me for this purpose the patient has remained absolutely well. It is now eighteen months since operation.

In answer to a question, Dr. Watson said the first patient had not been on a restricted diet since six weeks after the operation.

DR. C. B. PORTER showed a patient and related the following history: This man, seventeen years ago, was standing in a stooping position when his revolver of calibre 45 went off, the bullet passing along the ribs and lodging under the shoulder-blade. He has been operated upon three different times where it was supposed the bullet was lodged. He was troubled, because any motion of the arm brought friction of this bullet upon the ribs and upon the under surface of the scapula. He had these photographs taken in New York, which located the bullet on the second rib and in the subscapular space. I made an incision here four days ago, through the trapezius and came upon the interval between the levator anguli scapulae and rhomboids and entered the finger under the shoulder-blade. My finger was not long enough to reach the bullet, but my assistant, Dr. Newhall, reached it. I

enlarged the opening, and by carrying the arm as far as possible upward I dug out the bullet with my finger. I could not extract it with instruments. The muscles grasped the finger as the os uteri does when trying to dilate it. The wound is practically healed, and he has come to show the result of the recent operation. Here are two pictures of the case.

I have only a word to say, and that in the way of the practical application of what we have had demonstrated by x-rays. I think we realize what Dr. Richardson has said, that we want to know what is to be our method and a method which can be carried out by all surgeons with reference to the treatment of fractures. They must all be examined to know if they are in good position, or they will be examined afterwards and it may be proved against us that they are not in good position. It is a very important question which must be settled, probably be settled in favor of the x-ray picture. I do not mean to say we do not all wish to use it in difficult cases, only we have so many good results without it that it seems as if it would be unnecessary in all.

I have one picture here which will illustrate another side of the question, and that is the disorganization of bone by the advance of disease. This is from a case of advanced tuberculosis of the elbow and it shows the distance to which the ends of the bones have been separated by the increase of new tissue between them, or by the gradual destruction of a portion of the bone. This seems to me also an important advance and an aid in diagnosis. I have another radiograph showing the pleasant side of the question. It is the photograph of an elbow-joint in a subject of compound dislocation of the forearm backwards with fracture of the olecranon some years ago. I reduced the dislocation, put the olecranon in place and wired it to the shaft of the humerus. The silver wire was left in position permanently and shows in the picture. Perfect motion resulted.

DR. FRANCIS H. WILLIAMS: Allow me to refer to one of three cases of aneurism, two of which were aneurisms of the aorta and one of the carotid artery, which I have examined by means of the x-rays, using both the fluoroscope and the radiograph. The first case is that of a patient of Dr. F. C. Cobb's, whom Dr. Codman brought to the last meeting of this Society, and of whom I took a radiograph the next day at Dr. Codman's suggestion. In taking this radiograph the photographic plate was placed under the patient, who was lying on his back. This small photograph is a picture of the patient's back; to make it I looked at the patient with a fluoroscope and drew with a suitable pencil on the skin the outline of the aneurism as seen in the fluoroscope, and then photographed the line thus drawn. The point indicated by an arrow directs attention to the point of the curve of the aneurism where the pulsation was most marked. I supposed that the pulsation of the wall of the body of the aneurism would be more obvious than it was; but on reflection it is easy to see, I think, why this was not the case in the shadow of such a body. It is where the aorta is more nearly of normal size that the pulsations seem to be most marked. The curve seen in the radiograph is not quite the same outline that I saw in the fluoroscope because in the fluoroscope the shadow upon the aneurism was cut by a plain surface whereas the line shown in the radiograph was the line which this irregular surface of the back made in inter-

secting or cutting through the rays coming from the aneurism. The curve that I saw in the fluoroscope was rather more like the curve shown in the radiograph.

Dr. J. C. WARREN read a paper on

THE TREATMENT OF ACUTE INTUSSUSCEPTION.¹

Dr. ROTCH: It seems to be a very important question whether a case of this kind should be operated on and what to do when first called to see such a case. These cases almost always occur most frequently in infants at about the fifth or sixth month. It rarely occurs earlier, and one of the reasons that it occurs in infancy more frequently than at a later period is that the large intestine in proportion to the small intestine is shorter and the mesentery broader than at a later period, thus giving greater play in the region of the cecum and the colon where these intussusceptions usually take place. At this period of life the individual dies more quickly.

According to my observation, even when the infants are able to nurse and have a fairly good appearance, they may within a half-hour die suddenly with such a condition as this in their abdominal cavities. It is, therefore, very important to have some definite idea, first, as to the diagnosis, and then as to what shall be done in the especial case. It almost always occurs in perfectly healthy infants so far as can be ascertained by careful examinations both before death and at the post-mortem examination. The diagnosis of these cases is exceedingly simple. It appears to me that it is the first case of the kind which the physician sees that seems difficult to diagnose: a little uncertainty as to what he is dealing with, a little uncertainty as to whether he shall perform such a radical operation as laparotomy at once or later. A number of cases have come under my observation which I think will be interesting to speak of and certain points in connection with them which make it comparatively clear what course we should pursue in the individual case.

In the first place, as to the diagnosis. There is no other disease in which an infant will be attacked so suddenly with the clinical symptoms of abdominal pain combined with discharges of blood from the bowel. It is exceedingly rare for a young infant with gastro-enteric disease to present these symptoms very quickly. Until something is felt in the abdomen, however, we feel that we are not justified in making definitely our diagnosis. The diagnosis, however, even previous to the detection of a tumor, can be fairly made by any one who has seen a number of infants with intestinal disturbance; and this simple combination of abdominal pain and frequent discharge of blood, the discharges at first fecal mixed with blood, then pure blood, and then the blood mixed with mucus which gives the appearance of currant jelly, is almost characteristic after the first twelve, eighteen or twenty hours of the attack. You do not see it in any other disease at such an early period of the attack. When a tumor can be felt, of course the diagnosis becomes clear. The tumor, as a rule, in these cases is not felt early in the attack, even on careful examination, when the abdomen is not distended and when it is soft; it is also, as a rule, not detected for perhaps six or eight hours, that is by external manipulation; and by the rectum it often is not detected at all, even when the

¹ See page 125 of the Journal.

disease is fairly advanced. I have known a number of skilful examiners fail to detect the tumor by rectal examination when it was very evident that a tumor was present as shown by external examination.

Hydrostatic pressure, although not so much favored as formerly, would be comparatively safe to try in the beginning in the first six, eight or twelve hours of the attack. In experiments on the cadaver I have found that a column of six feet is held by the intestine, but it is wiser perhaps not to use more than four or five feet, also to allow for transudation which may take place, and therefore you should use a fluid to which there would be no objection if it entered the abdominal cavity. The hydrostatic pressure is usually unsuccessful in these cases. Dr. Stickney, of Arlington, just had a successful case, but the reduction by this means is rather rare and a good deal a matter of chance. It is almost always the case with an intussusception that that part of the intestine is not on a line with the axis of the intestine, but at an angle; and when you employ hydrostatic pressure it increases the trouble, presses the intussusception closer together and prevents the reduction. Also, beyond a certain time it is not only dangerous from possible rupture, but also is of no use whatever on account of the adhesions which have taken place. In the very early hours where adhesions have not taken place, it seems to be a perfectly legitimate procedure, but if it is not successful it would seem to me that immediate laparotomy is indicated. As to when adhesions take place it seems they evidently do so very early, within twenty-four to thirty-six hours at most, so that you cannot really operate too soon. It is better to operate while the infant is in fair condition, before it is reduced to this condition of the intestine which is conducive to reducing its vitality so quickly and to so quickly killing it.

The first case usually puzzles the diagnostician. Men seem to be staggered by their first case of intussusception. I remember some eight or ten years ago seeing my first case, with the usual symptoms. A perfectly healthy infant, six months old, breast-fed, was suddenly attacked with abdominal pain, with discharges of a currant-jelly consistency. During the first six hours nothing was to be found in the abdomen; at about the tenth or twelfth hour a tumor was found in the left side of the abdomen, and nothing felt by the rectum. I made a provisional diagnosis of intussusception; but I was uncertain what I was dealing with, and called an older physician, who said it was a case of dysentery. It is not so very unusual to have opinions of that kind given. I was still uncertain, and telegraphed for another physician to come, who immediately made the diagnosis of intussusception, and we used hydrostatic pressure at once, but without success. We then decided that an operation should be performed; but it was decided to wait for six or eight hours and see if it would be reduced spontaneously. Six hours later the infant had been nursing, was looking fairly well, and I felt comparatively easy about it. Fifteen minutes afterwards it died suddenly. The autopsy showed an intussusception through the ileo-cecal valve, and at such an angle that the hydrostatic pressure increased the difficulty of reduction. There were some adhesions; this was forty-eight hours from the beginning of the attack. With difficulty the adhesions were broken up and the intestine reduced, so that it was a case where laparotomy in all probability, even as late as forty-eight

hours, would have been successful even though adhesions had taken place.

The next case was one of the same kind, a healthy infant six months old, breast-fed, seen by two physicians in the central part of the State, one of them having the largest surgical practice in the district. The younger man supposed it might be a case of intussusception; the older man said that it was not. When I saw the case it was very easy to make the diagnosis. The tumor could then be felt, and by the rectum you could feel the invaginated intestine, and a currant-jelly material would appear on the examining finger. We then decided to have more advice. We telegraphed for one of our surgeons from Boston, who arrived sixty hours from the beginning of the attack and performed laparotomy. An extensive intussusception, involving about eight inches of the small intestine and passing through the ileo-cecal valve, was found. The surgeon tried to reduce it. There were some adhesions and a great deal of congestion; and he worked two hours on the case, and then tore a rent four inches long in the intestine. The reduction of the first four inches was comparatively easy; it then stopped; the cecum seemed to be inverted on itself. The intestine was stitched; the dressings were applied; and the infant began to nurse, looking fairly well.

But an hour afterwards it died suddenly.

These cases impressed upon me the necessity of not waiting. It is a perfectly simple diagnosis to make; and if the hydrostatic pressure does not reduce the intussusception, laparotomy should be performed at once. There are a very few cases on record where these infants live without operation, and they are liable to die any minute after invagination has taken place. I feel very strongly that an operation should be performed at once.

DR. C. P. PUTNAM: The case Dr. Rotch referred to occurred many years ago, and some of the details I cannot recall. The patient was a baby. I do not remember how long the case had run since the first symptoms came on, but I remember that the diagnosis was plain, because I could feel the tumor. Another physician had been there before, and had tried to reduce it by hydrostatic pressure, and had not succeeded, and they had waited a while.

Unless you have some means of plugging the anus without producing pain, it is impossible to have the water go in satisfactorily. For this purpose I placed a rubber bulb on the end of the fountain syringe and put into this bulb a short tube to go into the anus. This bulb is soft and compressible. When it is pushed against the anus it fills it up at once and then the anus dilates and it goes in farther and farther. It is evident that approximately speaking the same amount of force is used to hold in this soft plug that is used to dilate the bowel. If you press it in too hard your fingers compress the bulb; if you do not press enough the water comes out. There is no possibility of pushing too hard, because you are pushing with the same force that is distending the gut.

At that time operations were not very common on infants. I had not realized that they had been so rare in Boston now, as Dr. Warren told us. It was then considered a very dangerous procedure, and at the moment it seemed to me the only thing to save the child was to use hydrostatic pressure. The height of the column was considerably higher than mentioned by Dr. Rotch. The bag must have been seven feet

from the floor. The only gauge I had as to the possibility of danger was holding the hand on the abdomen and when the abdomen seemed to be distended too much I had the bag lowered. In a few minutes we took it down and let the water run out, but there was the tumor still. It was done once or twice more and then there was no tumor to be felt; the child fell asleep, was comfortable, went to bed and was well almost all night, but toward morning was in pain and on examination the tumor was again to be felt. We tried the water again in the same way and the tumor disappeared and did not reappear. I think, as Dr. Rotch says, it is a dangerous procedure and that the time very soon arrives when it cannot do good in any case because the intestines get swollen and brittle. In some cases it cannot do any good at any stage, and while I should try it in every fresh case because it is safer than opening the abdomen, yet opening the abdomen is a small matter compared to what it used to be.

DR. ROTCH: Was an opiate given after the first reduction?

DR. PUTNAM: I cannot remember.

DR. ROTCH: I think it is a very wise procedure, because local peristalsis is supposed to have something to do with it.

DR. WATSON: There is only one point to which I should like to refer, and that is with regard to a bit of surgical technique in operating for this condition which was suggested by Dr. Monks in a case of his. The invagination in his case, was of the small intestine through the ileo-cecal valve and the entire colon, and protruded through the anus. Laparotomy was decided upon, after ineffectual efforts to reduce the invagination, and was performed successfully so far as concerned the withdrawal of the invaginated portion, but the child died after a few hours. The operation was rather long, and what struck him, as it struck me and others at that time, was the great degree of collapse and prostration occurring in the young child, which, in addition to the manipulation of the bowel occurs because of the difficulty of keeping the child warm and protected while operating upon its abdominal organs. Dr. Monks suggested that it would be well to operate with the patient in a hot bath, and it seemed to me that it might be a valuable procedure.

DR. FITZ: Dr. Warren is to be congratulated upon the success of his treatment. The case reported by Dr. Stickney well illustrates the advantage, at the outset of cases of supposed intussusception, of a trial of hydrostatic pressure before resorting to laparotomy as a means of relief. Its frequent inefficacy is due, in part, to the failure to employ some such measure as that suggested by Dr. Putnam to prevent regurgitation of water from the bowel. Another explanation for the different behavior of intussusceptions under hydrostatic pressure is to be found in the seat of the lesion. If the obstruction is at the ileo-cecal valve as is frequently the case, the cecum itself is often involuted and the reduction is then much more difficult than when a portion of the colon only is invaginated into itself. I do not think the difficulty of reduction due so much to the formation of adhesions as to the resistance of the mouth of the sheath, partly from congestion and edema and in part from the traction upon it of the tense mesentery. Even at a post-mortem examination it is often not easy to pull the intussuscepted portion out of the sheath; one has to retract the latter from the intussuscepted bowel.

As to the time when the intussuscepted bowel should be operated upon, this is a matter which one cannot fix absolutely. In general, of course, the earlier the operation the more likely is it to succeed. Within the first twenty-four hours any adhesions which may have formed are easily torn. After a time the sheath becomes weak and the danger of its rupture from hydrostatic pressure is direct. In those cases where the intestine is torn at an operation the injury is due largely to traction upon the intussuscepted bowel, whereas the sheath should be moulded and withdrawn. In the first twenty-four hours an attempt should be made to reduce the intussusception by hydrostatic pressure and if this prove inefficient, laparotomy should be performed without further delay.

DR. WARREN: One or two points about the technique of the operation. In regard to taxis. Dr. Fitz's remark about the condition of the mouth of the sac describes a condition which I experienced in endeavoring to start the reduction. The mouth of the sac seemed to narrow as it approached the invaginated portion. There seemed to be a certain rigidity at this point of the bowel. In reducing, the custom is not to use any traction whatever on the intussusceptum because that is the strangulated part and may be easily lacerated. That must be held with the thumb and finger of one hand, and then the sac should be grasped by the other and traction or a squeezing motion exerted upon that. What I tried to do was to draw upon the outer wall and to force back its contents at the same time. Failing to do that in one of the operations I passed my finger round the ring, drove out some of the fluid from the meshes of the tissue, eased the tension at that point and then the rolling motion began and reduction was effected. It is a manipulation somewhat similar to that employed in strangulated hernia so far as the right hand is concerned, in fact so far as the left hand is concerned also, except that there is a pulling as well as squeezing motion.

DR. E. A. CROCKETT read a paper on

SYPHILIS OF THE EAR.²

DR. H. L. MORSE: The first case in which I used pilocarpine was a day laborer who, as I remember the case, had no history of syphilis, and who was supposed to have had a sunstroke. On a hot summer day he was wheeling a wheelbarrow over an exposed piece of ground, over and over again, and suddenly fell over his wheelbarrow, and was picked up and carried home. He was very, very dizzy, so that for a number of days he could not leave his bed. After a time he came to me accompanied by a friend. I cannot say positively that he had not had syphilis. My impression of the case is, that there was no history of syphilis. I gave him three doses of pilocarpine, small doses, at my office, and he waited while he went through his sweat. Three doses straightened him out so that his hearing was so good that he considered it normal; his dizziness was so far gone that he did not notice it at all. This is a case where I am pretty positive that there was no syphilis, and there seemed to be a good result, in an acute case, from three small doses of pilocarpine.

A year or two ago at the Eye and Ear Infirmary for a period of three or four months we tried giving pilocarpine to all the well-marked cases of tinnitus, dizziness and deafness that would submit to it. I have

² See page 128 of the Journal.

not the data to say exactly what the results were. They were exceedingly favorable if you can take the word of the patient for the results. The treatment is not a pleasant one, and I am not sure that some of the patients did not say they were less dizzy, because they did not want to go through more of it; but a very large proportion of those cases reported great diminution of dizziness and tinnitus, and in a number of the cases improvement in hearing after the use of pilocarpine subcutaneously. Those were not selected cases, as being syphilitic; I dare say many of them were. They were not selected cases as being recent. We took them as they came along in the clinic, and a great many of them had been there for months, and some of them for years being treated with a catheter and the ordinary middle-ear treatment, and a number of these reported that the improvement under pilocarpine was greater within two or three treatments than it had ever been in the ordinary middle-ear treatment.

I am sorry I did not know what train of symptoms Dr. Crockett was going to bring up, because I think I have the data which were made out for me by Dr. Hammond. I think there must have been twenty or thirty of those cases. I should, therefore, be inclined to try the pilocarpine a little more widely than Dr. Crockett has suggested in his remarks. I think it is worth trying in cases where we do not find a history of syphilis, or do not suspect syphilis. As he said, even where there is no improvement in hearing, there is an improvement in vertigo; and that alone is enough and makes it worth a trial. I have seen several cases of apparent total loss of hearing and total loss of bone conduction, in persons who were syphilitic, coming on during sleep. The persons went to bed hearing as well as they usually do, and awoke totally deaf and without any vertigo. Several cases of that sort were cases where the patient was known to be syphilitic, but had had no history of previous ear trouble.

DR. CROCKETT: The point I wished to make in the paper was not so much the improvement we obtain in many cases by the administration of pilocarpine, as that this particular complex of symptoms was apt to mean syphilis, and was apt to need pretty immediate treatment to restore the hearing. In most of the cases I have seen where the symptoms have been neglected a month or more the treatment has been hopeless. I once saw a case of hereditary syphilis in a child about twelve years old. One night, three or four months before she was seen by Dr. J. O. Green at the Infirmary, she went to bed perfectly well, and woke up perfectly deaf with loud tinnitus. She went on about a month, the cause not being recognized, when the process was repeated in the other ear. After another month she came to the Infirmary. Her father gave a clear history of syphilis before his marriage; no treatment; the mother had several miscarriages, and this was the first living child. She had had some few symptoms in infancy. She was a bright child, totally deaf. Treatment of every sort failed to improve her in any way, either as regards the vertigo, tinnitus or deafness. I think it was a case of the sort I have spoken of to-night, allowed to run too long.

PROFESSOR VIRCHOW RE-ELECTED. — Professor Virchow has been re-elected President of the Berlin Medical Society.

Recent Literature.

Gesundheitsbüchlein. Gemeinfassliche Anleitung zur Gesundheitspflege, Bearbeitet im Kaiserlichen Gesundheitsamt. Berlin: Julius Springer.

This health manual issued by the German Health Department of the German Government is a compact volume of 254 pages, containing the general principles of Hygiene, and is admirably adapted for use in the public schools. A good American edition, adapted to American needs, would prove extremely useful. The subjects treated are an opening chapter on the structure and functions of the organs of the body; the essentials of life, air, water and food; clothing; the house; exercise; man socially considered; settlements; commerce; training of children; employment and wages; danger from external causes; weather and climate; infectious diseases; other diseases; accidents; nursing.

The introduction is a model in its way, as the following extracts will show:

"The health of man is a precious possession. Its loss causes harm not only to the individual, but also to the community. The individual whose health is impaired suffers discomfort or pain. He loses his ability to work, or to earn a living, and his enjoyment of the pleasures of life. He must incur expense in order to regain his health, and anxiety and poverty are the results, both to himself and to his family.

"By the decrease of its productive labor, the community suffers loss in its industries, and incurs expense in the support of the sick; and when, as often happens, the sick man is attacked with an infectious disease, he becomes a danger to his neighbors. The extent of the loss arising from the impairment of health, can be estimated from the returns of the workmen's sick clubs of Germany. In 1891, out of a total membership of 6,500,000 more than 2,000,000 cases of illness occurred, each of which averaged seventeen days in duration. These clubs paid in medical expenses \$22,000,000. Since it may be assumed that, among the remaining 44,000,000 of the German population, 24,000,000 of whom are old enough to work, the cases of illness were as numerous and as long-continued as among the members of these clubs, the expense caused by sickness in Germany in 1891, is not placed too high at \$120,000,000. The loss incurred by stoppage of wages is not included in this sum.

"The preservation and promotion of the health of mankind is the aim of hygiene. Among the tasks which it proposes are the prevention, limitation and removal of sickness and disease, and the preservation and prolongation of the ability to work, and of man's life in general. . . . For a full understanding of the requirements of hygiene, a knowledge of the nature and organization of the human body is necessary."

The manual is illustrated with appropriate cuts and plates.

THE CZAR'S HEALTH. — The report that Dr. Von Bergmann had been summoned to St. Petersburg to remove an osteoma from the head of the Czar is now officially denied. He is reported to be free from the symptoms of any malady whatsoever.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, FEBRUARY 11, 1897.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.**SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.**All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.**All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.**Remittances should be made by money-order, draft or registered letter, payable to*DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.**CO-OPERATIVE ACTION FOR THE IMPROVEMENT OF MEDICAL EXPERT TESTIMONY.**

At a recent meeting of the Councillors of the Massachusetts Medical Society, the following resolutions and vote were passed unanimously:

Resolved, That the Councillors of the Massachusetts Medical Society regard with cordial favor and approval any just and practicable plan designed to improve the rules under which medical experts are employed in the courts.

Voted, That the Standing Committee on State and National Legislation be instructed to co-operate with the committees chosen by other associations, legal and medical, to promote legislation for the amendment of the methods in vogue relating to the use of expert witnesses.

At the meeting of the Massachusetts Medico-Legal Society on February 3, 1897, the following vote was unanimously passed:

Voted, That the Executive Committee of this Society be instructed to co-operate with committees chosen by other associations, legal and medical, in promoting legislation for the reform of the methods now used in the employment of medical experts in courts of law.

The Boston Medico-Psychological Society had previously appointed a representative committee the purpose of which is not to initiate action, but to co-operate with the Executive Committee of the Boston Bar Association in promoting legislation for improvement in the present laws relative to medical expert testimony, and we are informed that such co-operative efforts in this direction are now in progress.

The evils connected with the present system, which arise in the main from the fact that at present experts, often against their will, are made to appear as partisans of the side for which they are called, have long been realized by the medical profession, and have recently been discussed in our editorial of January 7, 1897, on "Medical Expert Testimony in Hypothetical Cases," and in an article on "The Opportunities and Responsibilities of Neurological Experts with Regard to Medico-Legal Testimony," by James J. Putnam, M.D., in our issue of October 22, 1896. Both these articles have suggested the advantages which would be gained if

the experts, instead of being restricted to the answering of hypothetical questions so framed by counsel as to accentuate their differences of opinion, were allowed to fully explain and discuss the case, a proceeding which would often bring out their points of agreement, and prevent their differences from standing out in full, and often partially false, relief.

The proposal which has been frequently made to have medical experts serve as advisers of the court instead of being retained by the plaintiff and defendant, and thus in a certain sense appear as partisans, and which many of the best men in the medical profession feel would be an advantage for the ends of justice, has been met on the part of the lawyers by the statement that the restriction of medical expert testimony to that of experts summoned by the court, would interfere with the fundamental right of the litigant to summon whom he chooses to testify in his behalf.

It was suggested, however, as long ago as 1872, that the summoning of medical advisers by the court need not interfere with the calling of experts by the plaintiff and defendant. The trial of Leavitt Alley for the murder of Abijah Ellis in Cambridge at that time aroused such interest on the part of the late Dr. Henry I. Bowditch in medical expert testimony that he asked Dr. Hildreth, of Cambridge, who made the autopsy on Ellis, to appear before the Boston Society for Medical Observation. Probably no committee of the Society was appointed at the time, but Drs. Bowditch and Hildreth saw Judge Joel Parker, and Ex-Governor Emery Washburn, both professors in the Harvard Law School, and Dr. John Ordronaux, with reference to the matter. Judge Parker said that any change in the present methods would interfere with the right of every man to summon any one whom he saw fit to help his cause. Governor Washburn was in favor of continuing the present method of summoning experts, but thought that the judge should have power himself to summon experts, who should review the whole testimony and evidence of the experts called by the litigants, and also that the judge should be required to summon experts if either lawyer demanded it.

In 1880, the following form of an Act was adopted by the Massachusetts Medico-Legal Society, and urged before the Judiciary Committee of the Legislature:

AN ACT IN RELATION TO MEDICAL EXPERT TESTIMONY.*Be it enacted, etc.*

SECTION 1. In any action, suit, or proceeding, civil or criminal, in which the testimony of a medical expert witness is desired by the parties, they may at any time before the trial file in the clerk's office a written agreement that such witness shall be summoned, designating him by name if agreed upon. The clerk shall thereupon issue a subpoena to the person designated, to be served in the manner provided by law. As soon as may be after service thereof the witness shall make such examination of the case as may in his judgment be necessary and practicable, and he shall attend as commanded in the subpoena, and answer such questions as may be put in relation to the case.

SECT. 2. If no person is designated by the agreement of the parties, the court, or any judge thereof in chambers, or in vacation, in any county, upon the filing thereof, shall designate a proper person, learned in the science of medicine, to be summoned as such expert witness, and the clerk shall thereupon issue a subpoena as hereinbefore provided. If the parties do not

agree that a medical expert witness shall be summoned in the case, the court or judge, upon motion of either party and upon hearing, may determine the question, and may designate the person to be summoned, if any, as hereinbefore provided.

SECT. 3. Such witness shall be paid for his attendance, travel, and services, a reasonable compensation, to be allowed by the court and paid out of the treasury of the county. In all civil actions and proceedings the defeated party shall be liable to refund the amount so disbursed; and after final judgment an execution may issue against him therefor in favor of the county commissioners, or, in the county of Suffolk, the city of Boston.

SECT. 4. In any case the court, upon its own motion or for cause shown, may order more than one, and not exceeding three persons, to be summoned as medical expert witnesses; and such additional witnesses shall be designated and summoned, and shall perform the same services and receive the same compensation as hereinbefore provided.

SECT. 5. In any criminal proceeding the defendant may call and examine other medical expert witnesses in addition to those hereinbefore provided for, but at his own cost; and in such case other medical expert witnesses may be called and examined in behalf of the commonwealth.

SECT. 6. No medical expert witness shall be admitted to testify before any court or magistrate except as hereinbefore provided.

Although no immediate result followed this action, and although perhaps it may have been, in the light of its complicated legal bearings, unwise or premature, it has had its influence as one of the early efforts looking toward the improvement of medical expert testimony. The reception which it met has, however, probably operated to deter medical men from making any further efforts along exactly the same lines.

It is to be hoped that the present co-operation on the part of representatives of important legal and medical organizations may result in legislation which shall enhance the value of such testimony both for the medical and legal professions, and, last but not least, shall oftener result in justice to both plaintiff and defendant.

THE REAL REASON FOR THE PASSING OF THE GENERAL PRACTITIONER.

FROM time to time the enraged practitioner, or the statistically inclined editor of a medical journal, raises his voice in melancholy plaint and inveighs against the dread evil of Hospital and Dispensary into whose hungry maws, ever insatiable for material, he sees disappearing day by day the last remnants of the "general practitioner's" *clientèle*. To him no words are strong enough to express his condemnation of "misguided charities"; and in the blindness of his rage he totally overlooks a far more formidable antagonist who stands between the public and himself and takes more dollars from his pockets than any hospital clinic that ever existed. We refer to the wily patent-medicine man. Backed by the testimonials of a host of so-called "cures," both male and female, selected from the most prominent walks of life, he probably accumulates more money in a month than the average medical practitioner does in a year, for at no time within our memory has the craze for exhibiting their photographs with a neatly-worded and convincing testimonial appended as to the virtues of this, that or the other quack nostrum, been so rife among people whose

names are household words all over the country and whose influence among the masses is widespread. The unblushing manner in which women disclose to the general mass of readers of the daily papers the pathological workings of their genito-urinary apparatus and the marvellous relief which they obtain—as evidenced by the redundancy of mammary tissue exposed in the accompanying wood-cut—by merely purchasing a bottle of Mrs. Allslop's Ovarian Stimulator, after they have been for months exposed to the ruthless fingers of all the best-known gynecologists, is enough to bring a flush to the cheek of a pernicious anemic—but it doesn't, it simply sends hundreds of other suffering females in search of this wonderful remedy for their self-diagnosed complaints.

Not a day passes but the lay press contains a villainous reproduction of the face of some well-known divine, accompanied by a testimonial overflowing with exuberant gratitude for the remarkable manner in which Dr. Charcoal's Tablets have enabled him to overcome the ravages of a deadly disease whose nature was so obscure that it defied the skill of the most renowned specialists even to determine. Cheek by jowl with him will be imprinted the philanthropic features of some famous temperance advocate who testifies in language whose sincerity is beyond a doubt, that it is only through the constant use of Brown's Nervine Invigorator (mainly proof-spirit with a dash of gentian and hux) that he is able to withstand the strain upon his nervous system incident to his vigorous onslaughts upon the demon Rum.

Next to the pulpit, the stage furnishes the greatest number of promising wrecks who have been snatched from an untimely grave—or from the lunatic asylum, more's the pity!—solely by the use of Someone's Malt or So-and-So's Wine, the secret of whose virtue is beyond the chemist's art to discover, but which probably owe their wonderful therapeutic value to the fact that they are a little more stimulating than beer and a trifle less paralyzing than absinthe. It will not be overstepping the narrow bounds of truth to say that there is hardly an actor or actress, singer or songstress of any repute to-day, for whose power to entertain we are not indebted to the magic influence of some patent nervine or reconstructive.

Even the legal profession is not loth to lift its voice to swell the chorus of praise for services rendered by the various prominently advertised nerve-foods and panaceas; and not a few eminent law-makers unconsciously—but clearly—explain, in the exhaustive symptomatology which they detail of their sufferings previous to the use of one of these panaceas, that peculiar flavor of general paresis so characteristic of certain statutes governing the practice of medicine.

Now that athletics stand so conspicuously before the public, we are everywhere confronted by the beautifully portrayed musculatures of crack athletes who owe their wonderful powers of endurance to an occasional nibble at Blank's Comatogenous Biscuits washed down by two or three drops of Somebody's

Kola Preparation to whose superiority as a preventive of undue tissue waste, the lavish supply of muscles in which the athlete rejoices abundantly attests.

One cannot sit down in an electric car without being confronted by a galaxy of lithographic beauties singing the praises, in rubricated rhyme, of coal-tar products or cold cream; and beside them one beholds the smiling and scorbutic countenance of banker's or merchant's child—money no object—whose once feeble frame was coaxed into vigorous activity by some patent food, after it had nearly succumbed to the misdirected onslaughts of the best-known pediatricists.

The effect of all this upon the general public can be easily imagined. If the Rev. Dr. This or the Hon. Mr. That has been cured by somebody's nostrum, or if their babies are able to thrive vigorously upon a patent food, why shouldn't the humblest of these gentlemen's admirers and their babies do the same? They try one bottle—and keep on trying, just as they keep on buying lottery tickets, until their money is exhausted, and then—too poor to employ even the general practitioner, they turn in desperation to the dispensary and hospital clinics where they faintly hope that they may come in contact with some specialist who will, by mere bull-luck, be able to stumble upon a remedy for their complaint. Let the general practitioner be content!

MEDICAL NOTES.

FOR THE STUDY OF THE RÖNTGEN RAYS.—The budget of the Prussian government appropriates 50,000 marks for investigation on the Röntgen rays. The money is to be used for apparatus to be divided into a number of special appropriations.

AN ANTI-CIGARETTE BILL has passed the lower House of the Tennessee Legislature by an unanimous vote, and it is expected that it will also pass the Senate. It prohibits absolutely the sale of cigarettes and of cigarette papers in the State. The law is to come into effect May 1, 1897.

SMALL-POX IN PUEBLO.—There were 270 deaths from small-pox in Pueblo, Mexico, during the first half of January. Most of the sufferers are among the poorest class of the Indians, and the spread of the disease is ensured by the custom of carrying the dead to the cemetery in coffins on the heads of surviving friends.

THE FUNERAL OF PROFESSOR DU BOIS-REYMOND.—The funeral ceremonies of du Bois-Reymond took place on December 29th in the lecture hall of the physiological laboratory, Berlin. Dr. Bosse, the Prussian Minister of Education, represented the government, and there were delegates from many scientific and learned societies. The Reverend Professor Scholz made the chief address; and other speeches were made by Professors Warburg, Munk, Rosenthal, Fritsch and Pictet.

TRI-STATE MEDICAL SOCIETY.—The fifth annual meeting of the Tri-State Medical Society of Iowa, Illinois and Missouri will be held in St. Louis, April 6, 7 and 8, 1897. The President of the Society is Dr. A. H. Cordier, of Kansas City; and the Secretary, Dr. G. W. Cale, 4403 Washington Boulevard, St. Louis.

THE PLAGUE IN BOMBAY.—According to the official report issued on January 28th, there have been 4,396 cases of the plague in Bombay, and 3,275 deaths from that disease. At Kurrachee 694 cases and 644 deaths have been recorded. At Poonah there have been 65 cases and 60 deaths, and a few cases have occurred at Surat, Baroda, Ahmadabad, Kathiawar and Cutch.

THE HUXLEY MEMORIAL.—The *British Medical Journal* states that the sum received by the Huxley Memorial Committee now amounts to nearly £3,000. Mr. Onslow Ford, R.A., has nearly completed the full-size model of the statue which is to be placed in the central hall of the Museum of Natural History at South Kensington. The dies for the Royal College of Science medal are now being prepared by Mr. L. Bowcher.

FIFTIETH MEETING OF THE AMERICAN MEDICAL ASSOCIATION.—The Committee of Arrangements for the fiftieth meeting of the American Medical Association, to be held in Philadelphia, June 1, 2, 3 and 4, 1897, desire to announce that in addition to the regular order of exercises during the meeting of the Association, there will be for a week preceding and a week succeeding the Association meeting, special courses and clinics given in the various large teaching institutions of Philadelphia, without cost to visiting physicians. This course has been organized in response to the generally expressed wish that opportunities might be given to visiting physicians of taking clinical courses, for it is believed that many physicians from distant points would be glad to spend a week or two over and above the time occupied by the meeting in this manner. The Chairman of the Committee of Arrangements is Dr. H. A. Howe. For particulars apply to Dr. Edward Martin, Chairman of the Clinical Committee, 415 South 15th Street, Philadelphia.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, February 10, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 108, scarlet fever 42, measles 135, typhoid fever 8.

CHANGES IN THE CORPORATION OF THE MASSACHUSETTS GENERAL HOSPITAL.—Samuel D. Warren and George Wigglesworth have been elected Trustees of the Massachusetts General Hospital, to succeed Roger Wolcott and Thornton K. Lothrop, whose terms have expired.

THE BOSTON CITY HOSPITAL CLUB.—The City Hospital Club held its eighth annual meeting and dinner at Young's Hotel on Wednesday evening, February 3d. The President, Dr. F. W. Draper, was in the chair, and Drs. H. P. Walcott and Hon. H. H. Sprague were present as guests of the Club. Ninety members were present. After dinner the President in a short speech introduced Dr. H. P. Walcott, who responded to the toast of "The Massachusetts General Hospital"; Hon. H. H. Sprague, who spoke for "The Trustees"; Dr. C. F. Withington, who answered for "The Medical Side," and Dr. Paul Thorndike, who replied for "The Surgical Side." The loving-cup presented to the Club by its first President, Dr. C. J. Blake, was passed about, after which there followed speaking by Dr. G. H. M. Rowe, for "The Hospital"; Dr. M. D. Clarke, of Haverhill, for "The Country Doctor"; Dr. John G. Blake, for "The Nurses." The evening closed with remarks by Dr. D. W. Cheever and by Dr. G. W. Gay, the newly elected President.

A NEW NURSES' HOME FOR THE BOSTON CITY HOSPITAL.—At a recent meeting of the Boston Board of Aldermen, Mayor Quincy presented a letter from the Board of Trustees of the Boston City Hospital, informing him of their acceptance of the gift of \$100,000, offered them by the trustees of the estate of the late Ann White Vose, according to the provisions of her will. The gift was made, as previously noted in our columns, on the condition that some permanent building be erected for hospital purposes, to be known as the "Ann White Vose" building, and the trustees state that it was made also under the expectation that the building should be a nurses' home. The trustees, in their letter to the mayor, allude to the totally inadequate accommodations of the present nurses' home, and state that the gift would be sufficient to erect a building which would accommodate 90 to 100 nurses. They recommend to the city government an appropriation for the purchase of the estates on the corner of Harrison and Massachusetts Avenues as the only available and convenient site for the new building, which in this event would adjoin the present nurses' home, and could be connected with it by corridors. About \$100,000 would be required for these purposes. The matter was referred to the Committee on Finance. The erection of the new building will at the same time supply one of the most pressing needs of the hospital, and provide a suitable memorial of the public spirit and generosity of the giver.

RESIGNATION OF DR. COTTING.—Dr. Benjamin E. Cotting has sent in his resignation as curator of the Lowell Institute Lecture Course, to take effect next April. Prof. William T. Sedgwick of the Massachusetts Institute of Technology will be his successor.

THE CHIMPANZEE AT THE HARVARD MEDICAL SCHOOL.—Prof. Thomas Dwight gave an interesting lecture to the Second-year Class at the Harvard Medical School on the anatomy of the chimpanzee, and a

comparison between the anatomy of the higher primates and man. The lecture was illustrated by the partially dissected body of the chimpanzee which died recently at the Zoo in Boston, and was kindly forwarded to the Harvard Medical School by the proprietors of the Zoo, Messrs. Atkinson and Bostock, for post-mortem examination and dissection.

THE MAINE MEDICAL ASSOCIATION.—This Association has 327 active members, according to a recent official list.

NEW YORK.

A PROLIFIC CAT.—Among the archives preserved at the Oak Street Police Station is a record of the progeny of a pet cat which has been an inmate of the station-house for the past twelve years. The addition to it of a recent litter brings the number up to the remarkable figure of 283 kittens.

X-RAYS FOR BELLEVUE HOSPITAL.—The Commissioners of Public Charities have decided to have placed in Bellevue Hospital a complete Röntgen-ray apparatus. They very properly regard this as an economical measure, as the ordering of x-ray photographs from outside has already been an item of considerable expense, and the establishment of such a plant in the hospital will be of material practical assistance to the medical and surgical staff.

THE BERTILLON SYSTEM.—Dr. Stephen G. Cook, President of the Board of Police Surgeons, who has been making a thorough study of the subject, both theoretically and in its practical application in Sing Sing prison, has, at the request of the Board of Police, established a bureau for the Bertillon method of measuring criminals, in connection with a photograph gallery, on the top floor of the Police Headquarters Building.

THE NEW YORK ACADEMY OF MEDICINE.—At the meeting of the New York Academy of Medicine held February 4th, the retiring President, Dr. Joseph D. Bryant, made some valedictory remarks, and the President-elect, Dr. Edward G. Janeway, was inaugurated. In the course of his address Dr. Janeway referred to the desirability of establishing a pathological laboratory at the Academy for the service and convenience of the members, and also expressed the wish that a committee should be appointed to take into consideration the vexed question of medical experts in criminal trials and bring the matter before the Academy for general discussion.

STEPS TOWARD A NEEDED REFORM.—At a recent conference of the authorities of the Charity Organization Society and a committee, consisting of Drs. Burroughs and Washburne, representing the Medical Society of the County of New York, a plan of co-operation was agreed upon for preventing unworthy persons from longer receiving free treatment at the dispensaries and out-patient departments of hospitals. The fact that those able to pay are constantly patients at these charitable institutions has long been a crying

abuse, and it is claimed that the number of such beneficiaries is steadily increasing. In consequence, not only do medical practitioners lose their legitimate fees, but the dispensary physicians, who give their services gratuitously, are greatly overtaxed. The contemplated plan of co-operation has in view the appointment of an organized corps of investigators to examine systematically into the financial condition of all applicants for treatment at the dispensaries.

Miscellany.

LOUIS AGASSIZ.

THE following tribute to the late Professor Louis Agassiz, relating especially to the debt which all American teachers of science, and not least those who teach the science of medicine, owe to him as the introducer of the laboratory method of teaching, is taken from the Annual Report of the President and Treasurer of Harvard College:

It will be fifty years next September since Louis Agassiz was elected Professor in Harvard University. The Museum he founded in 1859 has developed into an establishment which has cost for its building, collections and library more than a million of dollars, and possesses also an invested endowment of nearly six hundred thousand dollars. All education in the United States and all American science are under the deepest obligations to Louis Agassiz. He introduced here in 1847 the laboratory method of teaching science. Properly combined with lectures it was the only method he believed in or ever used, and it is the only method now considered satisfactory or even justifiable. When he was appointed professor, there was no laboratory for students' use in the entire university, except the dissecting-room for human anatomy in the Medical School, where the work done was for the most part of a crude sort. The numerous well-appointed laboratories of to-day, not only in Harvard University, but in all institutions of the higher learning, and even in well-equipped secondary schools, bear witness to the importance of this reform in which Agassiz was a pioneer. He created in the university respect for the special student—the persistent student of one subject—for he demonstrated in many of his pupils the developing, refining, and exalting influence of the thorough study of any one great subject. He was not so careful to inquire what had been the previous academic training of a promising young man, as to make sure of his present capacity, enthusiasm and endurance. As a proper test of fitness for a degree he gave preference to one comprehensive examination covering a long period of study over a long series of examinations, each covering a short period of study. It was not till 1872, twenty-five years after his appointment as professor, that this method of examination was introduced into the university in connection with the degrees of Doctor of Philosophy and Doctor of Science. He set up a high standard of endowment and equipment in his department, and thereby raised the standard for all other departments, not only in his institution, but in all other American institutions of the higher learning. When by the unequalled influence of his enthusiasm and persuasive oratory, he procured great sums of money from the Commonwealth and from private benefactors for the building and endowment of his Museum of Comparative Zoölogy, he was making it easier for the departments of Chemistry, Botany, Physics and Medicine to obtain material support for their laboratories and collections. The friends of other departments had to exert themselves to keep pace with his achievements. Almost from the beginning of his life in this country he took a strong interest in the elementary and

secondary schools as well as in the universities, and was ever ready to give time and labor to any undertaking which promised an improvement in existing school methods. He was always ready to exert himself to promote the introduction of just methods of teaching Natural History and liked no audience better than an assemblage of school-teachers. The lesson he taught in this respect has been learnt but slowly. To-day, in spite of his example and its manifest effects, there are few university teachers who take the interest which Louis Agassiz took in the work of the elementary and secondary schools, or are willing like him to labor strenuously on their behalf. He believed that the teacher and man of learning should always be giving out as well as acquiring, always be imparting as well as absorbing, always be trying to do something to advance the knowledge of his subject or to improve the means of teaching it. He constantly dwelt on the importance of testing young scholars by their intellectual productiveness, as well as by their capacity to assimilate the productions of others. His doctrine and example in this respect had a very stimulating and invigorating effect at this university and at many others. In all these ways he was far in advance of the average American college teacher of that period; and being endowed by nature with an extraordinary personal influence over friends, neighbors, and even casual acquaintances, and with a prodigious energy in travelling, exploring, collecting and teaching, he aroused new intellectual interests all over the country, raised the popular conception of the man of science, introduced on a great scale improved methods of teaching the sciences dear to him, and gave a new meaning to the word teacher.

THE PLAGUE AND CLIMATIC CONDITIONS.¹

THE present outbreak of the plague in India suggests certain considerations with reference to the possible connection of its occurrence with climatic conditions. While it used to be thought that the plague could not occur in the torrid zone, it is now known, in view of outbreaks of the disease within the tropics in Arabia and India, that this rule does not hold rigidly. In Egypt the autumn seems to be the season in which the plague appears, and June the month in which it dies out. In Europe, outside of Turkey, the plague season has been summer and autumn. In India no direct connection with the seasons could be detected in the epidemics of 1815-21, the first outbreak concerning which we have trustworthy information, and of 1836-38. From all the data at hand, the general conclusion is that a moderately high temperature favors the development and extension of the plague, but extremes of heat and cold are unfavorable to its breaking out. Exceptions to this rule are many. For instance, in the epidemic at Smyrna in 1735, the heat was so excessive during the plague that many of the people who left the town for neighboring villages died of sunstroke on the way, while in Roumelia, in 1737-38, the plague continued in many places in which the temperature fell at times to 3° Fahr. Regarding the effect of atmospheric moisture there is also some doubt. Some authorities hold that a high degree of humidity is necessary for the epidemic extension of the plague, while others maintain the opposite view. Certainly the occurrence of many outbreaks at high altitudes in Kurdistan, Arabia, China and India, makes it clear that a moist atmosphere is not always an essential in the spread of the epidemic. The present outbreak in India, coming at a time when medical men in that country and all over the world are thoroughly alive to

¹ R. DeC. Ward: Science, February 5, 1897.

the importance of studying the climatic relations of the disease, will undoubtedly result in giving us much additional information in this connection. The occurrence of this outbreak in India at a time of famine recalls the fact that the plague, 1815-21, broke out in the island of Cutch in a district where there had been a famine a short time before.

CHILD INSURANCE AND CRUELTY TO CHILDREN IN ENGLAND.

In the *Child's Guardian*, the official organ of the English National Society for the Prevention of Cruelty to Children, we find the following summary of the work of the Society since 1884:

"Since its formation in 1884, the Society has investigated 106,554 complaints of cruelty, of which 96,914 were found to be true, and affected the welfare of 259,336 children and 136,316 offenders. Action was taken as follows: 70,756 cases were warned; 12,128 were prosecuted (over 95½ per cent. being convicted); 14,000 were dealt with in other ways; 2,199 years of imprisonment and £3,886 in fines were inflicted; 54,760 children were known to be insured for a total sum of £277,000."

The large number of insured children (54,760) certainly points strongly toward the pernicious effects of child insurance. The classification of complaints was as follows: Neglect and starvation, 68,105; ill-treatment and assault, 21,643; manslaughter, 22; abandonment, 1,803; exposure, 3,909; causing to beg, etc., 5,027; indecent assault, 845; criminal assault, 611; immoral surroundings, 2,221; other wrongs, 2,368; 1,347 children died of their treatment.

THE PURPOSE OF PHYSICAL PAIN.

DR. WEIR MITCHELL's poem on "The Birth and Death of Pain," read at the recent Ether Celebration at the Massachusetts Hospital, has given rise to much discussion, by no means new, in the daily press as to the riddle of the purpose of physical pain. It is suggested that pain is obviously intended as a warning of impending danger, an indication of the condition of injured structures and also an educator and means of discipline. To one class of thinkers this question is a part of the problem of the origin and purpose of evil.

A writer in the *New York Commercial Advertiser* treats of these questions, and especially of pain as an educator, in a judicious and suggestive way. As an educator pain can have no influence, in his opinion, that is at all commensurate with its intensity.

"In spite of the argument advanced to show the effect of pain on the adult of small intelligence, we are bound to fix the limit of its educational purpose to the period of early childhood—to the teaching of the child that fire, which destroys the continuity of tissue, hurts; that a fall is accompanied by sensations that are disagreeable; that sharp-edged tools, when awkwardly handled, have a distressing effect, and so on. It gives no warning, however, of other equally dangerous and similar agencies, as that water will drown; and gases in the stomach, over which the child can have no control, and which are wholly without danger, are as acutely painful as a cut or bruise.

"However, some measure of utility in pain, perhaps merely incidental, must be admitted. Yet it so often hap-

pens that the pain is not proportioned to the danger to be guarded against, so that often it does not reach its maximum of intensity until all possibility of protective or curative action is past, that it seems unwarranted to regard its chief purpose to be indicative. There are diseases of a most virulent type in which the pain is nothing like the ache of a tooth. A mere distention of the stomach is sometimes the cause of a deeper pain than a condition that is bound to be fatal. The consequences of a tight boot are never as serious as certain diseases of the lung tissue, yet the pain may be much less bearable. The pain of tuberculosis is at its height in the most hopeless stage, when blood-poisoning is established. As an indicator pain is a failure, being too utterly inconsistent and indiscriminate in its operations. In its care for the preservation of the race, nature has made the sexual instinct the strongest of all, stronger even than that of self-preservation. How absurd, then, to make the travail of child-birth the most exasperating. It serves no other purpose than to discourage child-bearing—unless, of course, we regard it as a vindictive punishment of women for Eve's failure to resist the allurements of knowledge.

"It is a common idea that sorrow is essential to an enlargement of the sympathetic nature, and therefore to the achievement of the highest in the realm of the poetical and imaginative. Doubtless, it is true that mental suffering chastens and purifies and exalts in some instances, though in others it makes querulous and selfish beings of previously tolerable persons, but there is little reason to think physical pain has so often that effect as to make the victims impatient and fretful, a nuisance to friends and a bore to themselves. It is either too uncertain in its effects, or too often it weakens the moral sense, to be regarded as purposeful in this direction. In short, conceding its occasional, but possibly accidental, utility, the purpose of pain is less clear than the purpose of the beautiful, of which Emerson asked, in effect, what could be the use of the infinite forms of beauty in the shells sometimes brought to the surface in deep-sea soundings.

"If customs are the index to belief, then nobody now believes pain to be either a punishment we should bear for our own good, or a means of education it is to our interest to welcome, since even the mandate that woman shall bear children in pain is daily defeated, and no voice is raised to protest; and since in every case the first effort of layman or doctor is to relieve the sufferer. Mankind seems to be united in the opinion that the greatest boon to man is the discovery of the anesthetic.

"Of such little benefit is pain compared with the injury it inflicts, it is probable that if the wisest and most dutiful of men, knowing all it is possible to learn, should have it in his power either to abolish pain or allow it to continue under its present laws, he would probably banish it with so glad a heart that he would not regret the loss of the educating influence of pain in childhood."

A STATIONARY POPULATION IN FRANCE.

SINCE the last census revealed the fact that the population of France was not increasing, and that even the law passed some years ago that every seventh child might be educated and boarded at school at the nation's expense, was not sufficient inducement to cause families of seven or its multiples to result from French marriages, the French have become seriously concerned over their unfruitfulness. It has been suggested that every year France loses the equivalent of a battle of Sedan in infants, premature and still-born babies; moreover, Germans and Austrians are sending out disquieting stories of the number of children they can produce and rear to manhood.

It is related, for instance, that a Vienna woman in her fortieth year recently presented her husband with

their thirty-second child. The effect of such stories upon the susceptible mind of the Frenchmen is tremendous. Suppose every married woman in Germany and Austria goes on at this rate, what will become of France?

Desperate efforts are made to rear infants under glass in the incubating establishment in the Boulevard Poissonnière, where, it is stated, all infants who are brought there immediately, without receiving a chill on the way, and exceed the small limit of two and one-fourth pounds in weight, are successfully reared. The managers of the institution state that they have saved the lives of 1,200 children since it was established.

The National Alliance for the Increase of the Population of France has this week presented a petition to the Prime Minister, setting forth certain drastic measures which the government is urged to adopt. Dr. Bertillon, inventor of the system of measuring criminals, is the head of the society, and its plan includes some interesting features. It proposes that government scholarships in schools, lycées, and academies be given only to families having at least three children living; all favors of government, such as tobaccoists' licenses, concessions in colonies, etc., to be given to such families; when the claims of government officials for promotion are decided, their number of children to be taken into account; allowances and traveling expenses to officials, as well as the salaries of subalterns, to be regulated according to the number of children; the posts under the government, except those requiring special qualifications, to be given only to fathers having more than three children.

BEHRING'S DIPHTHERIA ANTITOXIN SERUM IMPROVED.

PROFESSOR BEHRING announces in the *Fortschritte der Medicin* that he has succeeded in improving the diphtheria serum so that any ill effects will henceforth be entirely avoided. The undesirable symptoms observed sometimes, such as exanthems, swelling of the joints, albuminuria, etc., are, in Professor Behring's opinion, due partly to the diphtheritic process itself and partly to accessory products which are present in the serum, pure antitoxin being a definite substance which only acts against the virus of diphtheria, and otherwise has no influence on the organism. Professor Behring has not been able either to remove these products from the serum or to prevent their formation; but the strength of the serum, reckoned in antitoxin units, has been increased so much that only a small quantity is required, and the unpleasant symptoms referred to are not now produced. This extra potent serum is sold by the Hoechst factory as a dry preparation, which, before being administered, must be dissolved in water. It is very soluble, and may be kept for any length of time. It does not contain carbolic acid or any other antiseptic compound, but is simply preserved in hermetically closed bottles. The strength of one gramme is 5,000 normal units.

Professor Behring points out that the new antitoxin is especially valuable for immunizing purposes; the immunity obtained by its administration lasts about four weeks. He hopes that the small number of medical men who are still opposed to the antitoxin treatment will now be persuaded of its efficacy and safety.

Correspondence.

THE ELSNER METHOD OF DIAGNOSIS IN TYPHOID FEVER.

13 HEREFORD ST., BOSTON, MASS.

MR. EDITOR:—I am engaged, at present, in investigating the value of the Elsner method in the diagnosis of typhoid fever by the bacteriological examination of the stools. Unfortunately, for my purpose, the number of typhoid cases just now in the wards of the Massachusetts Hospital is very small. I should like, therefore, to say, through your columns, to the members of the profession, in Boston and immediate vicinity, that I should consider it a great favor if I were allowed to make, at short intervals, cultures from the stools of suspected typhoid patients.

It is especially desired to get cases as early as possible in the disease, but any case, up to the stage of convalescence, would be of value.

Any physician, who desires to co-operate with me, will kindly write to me at above address.

Very truly yours, MARK W. RICHARDSON, M.D.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JANUARY 30, 1897.

Deaths reported 3,105: under five years of age 1,015; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 317, acute lung diseases 555, consumption 352, diphtheria and croup 171, diarrheal diseases 61, typhoid fever 28, whooping-cough 19, scarlet fever 13, measles 12, erysipelas 9, cerebro-spinal meningitis 4.

From whooping-cough New York 6, Philadelphia 4, Baltimore and Washington 3 each, Chicago, Boston and Providence 1 each. From scarlet fever New York 7, Chicago and Boston 2 each, Baltimore and Lawrence 1 each. From measles Chicago 5, New York 4, Boston, Providence and Worcester 1 each. From erysipelas New York 4, Chicago 2, Philadelphia, Boston and Nashville 1 each.

In the thirty-three greater towns of England and Wales, with an estimated population of 10,992,524, for the week ending January 23d, the death-rate was 19.7. Deaths reported, 4,156; acute diseases of the respiratory organs (London) 325, whooping-cough 117, diphtheria 87, measles 67, scarlet fever 43, fever 36, diarrhoea 35, small-pox (London) 1.

The death-rates ranged from 12.0 in Croydon to 29.2 in Liverpool; Birmingham 21.8, Bradford 20.1, Brighton 14.2, Gateshead 16.0, Hull 16.9, Leeds 20.2, Leicester 20.5, London 18.1, Manchester 26.0, Newcastle-on-Tyne 19.4, Nottingham 19.7, Plymouth 18.2, Sheffield 21.2.

METEOROLOGICAL RECORD

For the week ending January 30th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 30, 1897, TO FEBRUARY 5, 1897.

MAJOR WILLIAM C. SHANNON, surgeon, will upon the expiration of sick leave, be relieved from duty at Fort Custer, Mont., and ordered to Jackson Barracks, La., relieving FIRST-LIEUT. ROBERT S. WOODSON, assistant surgeon.

FIRST-LIEUT. WOODSON, on being thus relieved, is ordered to Fort McPherson, Ga., for duty, relieving CAPTAIN PHILIP G. WALES, assistant surgeon.

CAPTAIN WALES, on being thus relieved, is ordered to Fort Niobrara, Neb., for duty.

MAJOR EDWARD B. MOSELY, surgeon, ordered, upon the expiration of his leave of absence, to Benicia Barracks, Cal., relieving MAJOR CURTIS E. MUNN, surgeon.

MAJOR MUNN, on being thus relieved, is ordered to Fort Logan, Col., for duty, relieving MAJOR AUGUSTUS A. DELOFFRE, surgeon.

MAJOR DE LOFFRE, on being thus relieved, is ordered to Fort Sam Houston, Tex., for duty.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING FEBRUARY 6, 1897.

H. LAMOTTE, assistant surgeon, granted sick leave.

SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY. — The Section for Clinical Medicine, Pathology and Hygiene will meet at the Medical Library, 19 Boylston Place, Wednesday, February 17, 1897, at 8 o'clock.

The following papers will be read: Short communications from Drs. Greenleaf and E. H. Nichols, and the paper of the evening by Dr. E. G. Cutler, "Chronic Gastric Ulcer."

Dr. Hewes will speak on "The Analysis of Gastric Contents."

E. W. TAYLOR, M.D., Secretary.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

The next lecture will be given on Thursday evening, February 18th, at 8 P. M., by ASST.-PROF. WM. T. PORTER. Subject: "The Physiology of the Sympathetic System." The profession are invited.

RECENT DEATHS.

SAMUEL HUTCHINS HURD, M.D., M.M.S.S., formerly of Charlestown, died at Atlantic City, N. J., February 5, 1897, aged sixty-six years.

CHARLES WENDELL COOPER, M.D., M.M.S.S., of Northampton, died at sea, February 7th.

BOOKS AND PAMPHLETS RECEIVED.

Eighteenth Annual Report of the State Board of Lunacy and Charity of Massachusetts, January, 1897. Boston: Printed by the State. 1897.

Gonorrhoeal Iritis and Non-Suppurative Gonorrhoeal Conjunctivitis and their Pathology. By William Cheatham, M.D., Louisville, Ky. Reprint. 1896.

Transactions of the American Ophthalmological Society, Thirty-second Annual Meeting, New London, Conn., 1896. Hartford: Published by the Society. 1897.

Impetigo Contagiosa Universalis. Treatment of Ringworm of the Scalp in Institutions. Some Glycosuric Dermatoses. By Charles W. Allen, M.D., New York. Reprints. 1896.

A Brief Note upon a Perfected Series of Test-Words Intended for the Determination and Estimation of the Power of Accommodation. By Charles A. Oliver, A.M., M.D. Reprint. 1896.

Transactions of the American Surgical Association. Volume XIV. Edited by DeForest Willard, A.M., M.D., Ph.D., Recorder of the Association. Published by the Association. Philadelphia: W. J. Dornan. 1896.

Abdominal Surgery. By J. Grieg Smith, M.A., F.R.S.E., Surgeon to the Bristol Royal Infirmary; Professor of Surgery, University College, Bristol. Fifth edition. Volumes I and II. London: J. & A. Churchill. 1896.

Note Climatologique et Démographique sur Biarritz. Par le Dr. Lobit, Membre de la Société Astronomique de France. Communication faite au Congrès d'Hydrologie, de Climatologie et de Géologie de Clermont-Ferrand (Septembre-Octobre, 1896). Biarritz. 1896.

Vingt Cas de Fractures de Clavicule Traités par le Massage. Par le Dr. Dagron, Ancien interne des Hôpitaux de Paris, Chargé du service des masses des fracture à l'Hôpital Beaujon. Extrait du *Journal de Médecine et de Chirurgie Pratiques*, 25 Aout, 1896. Paris: A. Coccoz, Libraire-Editeur. 1896.

De la Gonococcose — Gonococcite et Gonococcie, Localisations Gonococciennes et Infection Gonococcique. Par le Dr. Richard D'Aulnay, Ancien interne de Saint-Lazare. Extrait de la *Revue Internationale de Médecine et de Chirurgie*, 10 et 25, Décembre, 1896. Clermont (Oise): Imprimerie Dax Freres. 1896.

The Sequels of Disease, being the Lumleian Lecture delivered in the Royal College of Physicians, 1896, together with Observations on Prognosis in Disease. By Sir Dyce Duckworth, M.D., LL.D., Fellow and Treasurer of the Royal College of Physicians, etc. London, New York and Bombay: Longmans, Green & Co. 1896.

Objections to and Criticisms on the Majority Report of the Committee of the Medico-Legal Society on the Existing Law for the Commitment of the Insane. Practical Points Regarding the Senile Insanities, with Special Reference to Prophylaxis and Management. By Ralph Lyman Parsons, A.M., M.D., New York. Reprints. 1896.

Physiology for Beginners. By M. Foster, M.A., M.D., F.R.S., Professor of Physiology in University of Cambridge, and Lewis E. Shore, M.A., M.D., Fellow of St. John's College, Cambridge, and Senior Demonstrator of Physiology in the University of Cambridge. New edition, with additions. New York: The Macmillan Company. 1897.

Le Rôle de la Graisse dans les Hernies: Applications Thérapeutiques, Prévention des Hernies, Préparation des Sujets à Opérer, Traitement Palliatif des Sujets Inopérables. Par le Dr. Just Lucas-Championnière, Chirurgien de l'Hôpital Beaujon, Membre de l'Académie de Médecine. Extrait du *Journal de Médecine et de Chirurgie Pratiques*, 10 Septembre, 1896. Paris: A. Coccoz, Libraire-Editeur. 1896.

The Diseases of Infancy and Childhood, for the Use of Students and Practitioners of Medicine. By L. Emmett Holt, A.M., M.D., Professor of Diseases of Children in the New York Polyclinic; Attending Physician to the Nursery and Child's and the Babies' Hospitals, New York Infant Asylum, and to the Hospital for Ruptured and Crippled. With 204 illustrations, including seven colored plates. New York: D. Appleton & Co. 1897.

A System of Practical Medicine by American Authors. Edited by Alfred Lee Loomis, M.D., LL.D., Late Professor of Pathology and Practical Medicine in the New York University, and William Gilman Thompson, M.D., Professor of Materia Medica, Therapeutics and Clinical Medicine in the New York State University; Physician to the Presbyterian and Bellevue Hospitals, New York. Vol. I, Infectious Diseases. Illustrated. New York and Philadelphia: Lea Brothers & Co. 1897.

Original Articles.

VENTRO-SUSPENSION OF THE UTERUS.

BY JOHN C. IRISH, M.D., LOWELL, MASS.

THE term "suspension" rather than "fixation" is chosen, because suspension, with considerable mobility of the uterus is to be especially desired.

The manner in which the operation is usually done, gives fixation for a short time after; while the secondary effect is a suspensory ligament which allows considerable motion. Formerly, when fixation was especially aimed at and obtained, the after-results of the operation were much less satisfactory than they are now; so that, in suspension of the uterus most operators at this time employ a technique designed to avoid a permanent fixation, and secure suspension in the ultimate result. Still, in the matter of technique, there are certain details of the operation by which we can save the patient some after-anoyance.

When the organ is suspended by buried silk or silk-worm-gut sutures, the latter occasionally make their way out through a suppurating sinus. These extrusions, of the silkworm gut especially, have occupied a very long time. I have had this unpleasant experience in several cases. Therefore, of late I have suspended the uterus with two kangaroo-tendon sutures carried through the abdominal muscles, "fascia" and "peritoneum," thence through the anterior portion of the fundus and through the muscles of the opposite side. I prefer to carry sutures through the anterior rather than the posterior portion of the fundus, believing that when the suspensory ligament has been formed, the uterus may be in a more nearly normal position.

A still more cogent reason for attaching the uterus to the abdominal wall by sutures through the anterior portion of the fundus is brought out by the investigations of Dr. Noble in a communication to the American Gynecological Society, May 27, 1896. Discussing the effect of suspension of the uterus upon pregnancy and labor, after an investigation of 808 cases, Dr. Noble deduced, among others, the following conclusions: "That serious or insuperable obstructions to labor may be produced if the fundus and anterior walls of the uterus are imprisoned below the point of attachment between the uterus and abdominal wall."

This one dystocia of pregnancy and labor due to suspension of the uterus, and the only one his investigations did unquestionably establish, seems really due to the introduction of the sutures upon the posterior surface of the fundus. This condition, as described by Dr. Noble, is due to a tumor at the superior strait, consisting of the imprisoned and hypertrophied fundus and anterior wall of the uterus, constituting a muscular mass, that obstructs the entrance into the pelvis.

I think we may, therefore, reasonably hope that sutures introduced upon the anterior portion of the fundus, may prevent the occurrence of this complication in a following pregnancy and labor. Should this be the case, from the 808 cases investigated by Dr. Noble I think we are fairly justified in concluding that the operation has no objection with reference to a following pregnancy and labor.

In the treatment of retro-displacements of the uterus, ventro-suspension has been so generally resorted to for the past few years, and the results have been so satisfactory, that its employment in these

cases is fast becoming a matter of routine practice. The operation can be very easily and quickly done, and, barring avoidable accidents, without danger to the patient. When we secure suspension rather than fixation, the relief is complete and permanent. The value of the operation in this class of cases is so well established that little remains to be said.

In the treatment of procedentia uteri of every degree, from moderate downward displacement to complete prolapse, the propriety of uterine suspension has not been so generally recognized as in case of retro-displacements. It is in this class of cases, that I wish to especially insist upon the value of this operation. Procedentia, occurring mainly among women of middle age or advanced life, who have borne several children, is very frequently met with. We see only exceptionally, the very aggravated forms of the disease, where the uterus is entirely prolapsed, accompanied by the bladder and a portion of the vagina. More frequently the mouth of the uterus descends to the vulva, and is arrested there. Whether this condition is still further complicated by cystocele depends much upon the condition of the pelvic floor and anterior vagina. The uterus is enlarged and congested, and necessarily retro-displaced. With this condition in these cases anterior and posterior colporrhaphy never cures; and when, in addition, the uterus is curetted and drained, and lacerations of the cervix repaired, if need be, still these multiple operations only partially correct the faulty conditions. It is true, however, they afford great relief—so great that the patients, whose condition has required some of these operations, have believed themselves entirely cured. The relief they experience may to a certain extent be permanent; but the faulty position of the uterus has not been corrected. It is still displaced backward, and is still much too low in the pelvis. Consequently, after a time the uterus descends again to its old position, and again becomes heavy and congested; while, if we have complete prolapse, the failure of all these operations is, as a rule, only more complete and prompt.

This statement of the inefficiency of the above plastic operations for the correction of procedentia uteri, is based largely upon personal experience. But in extenuation of my apparent lack of skill to obtain perfect and permanent results from these operative proceedings, I must say, that, so far as I have observed the cases of other operators, they have had much the same defective results as have followed in my own cases. While one or more of these operations in the vagina is usually necessary to restore the vaginal outlet or uterus to its normal condition, yet the prime object of our efforts must be to restore and permanently retain the uterus in its original position. This, ventro-suspension does with sufficient precision to make a permanent cure in cases of procedentia of the second degree.

My personal experience in the treatment of prolapse of the uterus by ventral suspension, comprises 21 cases. In 18 there was descent of the organ to the vulva. Three were cases of complete prolapse. Ventral suspension alone was done in the first five cases, with the belief, that when the uterus was held in position, all inconvenience from cystocele and defective perineum would gradually disappear. The after-results in three of these cases corrected that error. In one I have since done anterior colporrhaphy and perineorrhaphy. Two others are still suffering from a cystocele—but

not enough to induce them to have it relieved by operation. There are occasional examples of prolapse of the uterus to the vulva, in which there is no defect of perineum and no cystocele. In the treatment of these, ventro-suspension alone is required. Anterior and posterior colporrhaphy was done in most of the remaining 16 cases. An elongated cervix was amputated in one case. In several instances curetting and drainage of the uterus seemed necessary, and was done in addition to the plastic vaginal operations.

In brief, whatever operations upon vagina or uterus the condition of each patient seemed to require, were done first; then the uterus attached to the abdominal wall at the same sitting.

The after-progress of all these patients to recovery was rapid and uneventful. In no instance were there any of those disturbances that we now and then see after abdominal sections for other and graver affections. The contents of the abdomen are so little exposed and so little is done within the abdominal cavity, that there is no danger except from septic infection, which, with our care of to-day in this operation, is practically an eliminated factor of danger.

The recorded results in large numbers of cases by others, confirm this statement. Ventro-suspension, in addition to the ordinary plastic operations done for prolapse, did not in any way alter or retard the patient's progress to recovery. These cases have been operated on so recently that I do not know whether there will be any remote sequelæ that will detract from the value or final success of the operation. But its after-results so far have been so satisfactory to myself and so gratifying to the patients, that in all cases of prolapse of the uterus to the vulva, ventro-suspension will be done with the consent of the patient; and in view of the complete cure that can be promised, that consent will rarely be withheld.

As applied to the correction of complete prolapse, ventral suspension cannot be advised so confidently. Although it has been entirely successful so far as my own small experience goes, still there are several recorded cases of failure. Some of these are undoubtedly due to the fact that hysterorrhaphy alone, without the auxillary plastic operations, was relied upon.

We have, then, to compare ventral suspension, supplemented, of course, with the necessary plastic work, with other operative procedures that may be chosen for the treatment of the affection. Vaginal hysterectomy has given, in many cases, very satisfactory results, but it is often followed by an intractable cystocele.

The character of the operation is such that this sequel cannot be prevented nor cured when it has once occurred. Ventro-suspension, even if it is followed by an occasional relapse, is by far the preferable operation.

The choice of operation, then, lies between hysterorrhaphy and abdominal hysterectomy. Baldy reports eight cases of supra-vaginal hysterectomy for prolapse, and describes the technique followed, which in the first part, is the ordinary operation (Baer's). Then he raises and attaches the cervix to the broad-ligament pedicles that contain ovarian arteries and sound ligaments. He thus utilizes the remaining portion of the cervix to draw up and anchor the stretched-out vagina. The advantages of this procedure over complete abdominal hysterectomy are at once apparent.

In one case Baldy¹ attached the cervix to the anterior abdominal wall.

Noble² also reports a case in which hysterorrhaphy had failed, and in which he did hysterectomy and attached the cervix to the abdominal wall.

These cases all gave satisfactory results.

The single advantage of hysterectomy over ventro-suspension is that it would probably eliminate the rare failures that might follow the latter operation. A very movable uterus can be removed with great facility and with very little danger, still the mortality of the operation is necessarily larger than that of ventro-suspension. When it is done for prolapse, the patient must submit, two or three weeks later, to additional plastic operations, and is confined in bed six weeks. When ventro-suspension is done the patient is consciously disturbed by only one operation, for the others that are required are done at the same time, and she recovers in three weeks. At the present time, my own choice of operation will be ventro-suspension with women of child-bearing age, and those quite advanced in years, for example, sixty-five and older, and in ordinary cases of complete prolapse. Should prolapse recur, the failure is not irremediable, for hysterectomy can then be done. However, in that class of cases in which the uterus has become greatly enlarged or its structure much changed from long-continued exposure, I believe that hysterectomy with all its disadvantages will give better results.

ANATOMY OF CONGENITAL EQUINO-VARUS.¹

FROM THE SEARS PATHOLOGICAL LABORATORY OF THE HARVARD MEDICAL SCHOOL.

BY EDWARD H. NICHOLS, M.D., Assistant in Pathology.

THE two specimens of equino-varus illustrated in this article are the feet of a still-born child, delivered at term, in the Out-patient Clinic of the Boston Lying-in Hospital.

Besides the double club-foot there was a failure to close of the posterior wall of the neural canal in the occipital and dorsal regions, "partial cranio-rachischisis"; a lack of development of the right side of the heart, and a fetal mesentery.

The left foot was carefully dissected. The right foot was frozen, and cut in parallel sections in a plane corresponding to that of the malleoli. This method, so far as the writer knows, is a new one, and gives an accurate view of the relations of the parts, without the artifacts necessarily associated with any dissection of the deep structures.

THE NORMAL FOOT.

In the normal foot the astragalus lies tightly wedged between the tibia and fibula, with which its upper surface articulates, and this joint permits motion only in flexion and extension. In front of this joint the neck of the astragalus extends forward and slightly inwards, and terminates in an articular facet or head, which articulates with the scaphoid. The plane of this joint is practically at right angles to the long axis of the foot. The astragalus rests upon the os calcis, a little to its inner side, and the plane of the articular

¹ Read before the Boston Society for Medical Improvement, November 30, 1896.

² American Journal of Obstetrics, April, 1896.

² American Gynecological and Obstetrical Journal, May, 1896.

surface between the astragalus and os calcis is practically a horizontal one, at right angles to the long axis of the leg.

The os calcis lies below, and a little to the outer side of the astragalus, to which it is firmly attached by the interosseus ligament. The long axis of the os calcis runs forwards and slightly inwards. The anterior end extends nearly to the plane of the joint between the astragalus and the scaphoid, and articulates with the cuboid. The plane of this joint is also practically at right angles to the long axis of the foot. The two articulations, between the astragalus and the scaphoid on the inner side of the foot, and the os calcis and cuboid on the outer side of the foot, together constitute the "mid-tarsal" joint. This joint

calcis posteriorly, and the scaphoid and cuboid anteriorly. The deformity is best understood by studying the changes in the individual bones, ligaments and tendons. The following description of the abnormalities, especially of the relations of the bones, is based upon an examination of the two feet illustrated in this article, and of several dissections and preparations in the Warren Museum. For descriptions of individual bones various works were consulted, especially the admirable description of Walsham and Hughes.

The astragalus is deviated slightly inward at the ankle-joint, the neck is somewhat elongated, and curves inward and downward so that the facet which should articulate with the scaphoid, points inward. The whole astragalus is tipped forwards so that the ante-

Congenital Equino-Varus. View of anterior surface of left foot. Line-drawing from photograph of dissected foot.

allows limited motion in all directions, and is the joint chiefly concerned in the deformity of club-foot.

EQUINO-VARUS.

The gross changes in club-foot are obvious. The heel is small and elevated. In front of the leg the dorsum of the foot is prominent; the toes point inward nearly at right angles to the line of the leg, and the outer edge of the foot rests upon the ground, while the inner border is raised; the dorsum of the foot looks forward, while the plantar surface looks backward. The sole of the foot is contracted. The deformity is due to an inward and upward rotation of the whole foot, caused by a change in the shape of all the bones of the foot, accompanied by a contraction of the internal, and a lengthening of the external, ligaments, and by shortening of certain muscles and tendons, and by peculiarities in the course of vessels and nerves.

The greatest and most important abnormalities are the obliquity of the facets, and the change in shape of the bones which enter into the formation of the "mid-tarsal" joint, that is, the astragalus and os

Congenital Equino-Varus. View of plantar surface of left foot. Shows convexity of os calcis; altered relation of cuboid; and direction of posterior tibial tendon. Line-drawing from photograph of dissected foot.

rior half or two-thirds of the superior articular facet is not covered by the ankle-joint, and appears as a prominence on the dorsum of the foot. The inner surface is compressed, so that on cross-section the bone appears wedge-shaped, with the apex of the wedge on the inner side of the foot.

The os calcis is generally small. The posterior end is raised, the anterior end is depressed, while the bone, as a whole, is rotated inward beneath the astragalus, with the interosseous ligament as the axis. Moreover, the whole bone is convex externally and concave internally, and is directed downward, forward and inward, so that the anterior facet looks down and inward.

The scaphoid is somewhat flattened, is drawn inward and upward, and slightly rotated on its antero-posterior axis, so that its internal surface looks somewhat upward. It articulates with a facet on the inner side of the head of the astragalus, and may also articulate with the internal malleolus.

The cuboid is somewhat altered in shape, is drawn inward and upward, and is somewhat rotated on its antero-posterior axis, so that its internal surface faces

upward; it may be drawn entirely to the inside of the os calcis. It articulates with the obliquely placed anterior facet of the os calcis.

The cuneiforms are slightly changed in shape, the facets being obliquely placed to correspond with their altered position. They are adducted and rotated inward, so that their plantar surfaces look backward and inward.

The metatarsals are adducted and rotated to correspond with the altered positions of the cuneiforms and cuboid, but are only slightly altered in shape.

The internal ligaments are contracted, especially those which bind the scaphoid in its position. The external ligaments are lengthened. The plantar fascia is very much contracted.

The anterior tibial muscle is displaced inward, and shortened, and is an important factor in maintaining the varus position of the foot. The posterior tibial

that part of the foot in front of the mid-tarsal joint. The rotation of the anterior part of the foot causes the outer edge of the foot to bear upon the ground, and the dorsal surface to look forward. The shortened ligaments and tendons, especially those of the tendo-Achillis, tibialis anticus, and tibialis posticus, retain the foot in its abnormal position, while the shortened plantar fascia causes the contraction of the sole of the foot. Of these changes the most essential, and the one which offers the greatest resistance to correction of the deformity, is the obliquity of the mid-tarsal joint.

In patients who have walked upon uncorrected club-feet, all of these deformities are increased and accentuated. The muscles atrophy. The cartilaginous

FIG. 3. Congenital Equino-Varus. Frozen section through mid-tarsal joint of normal foot at birth. Shows articular facets of astragalus and os calcis, with plane of articulation at right angles to the long axis of the foot.

is shortened, and extends directly forward to its attachment to the scaphoid. The tendo-Achillis is shortened, and elevates the posterior end of the os calcis.

The anterior tibial artery is displaced inward, but is separated from the anterior tibial tendon by the long extensor of the great toe. The posterior tibial artery lies to the outer side of the posterior tibial tendon, although in close proximity.

The posterior tibial nerve is closely approximated to the posterior tibial artery.

Hence it appears that the deformity of the foot in cases of congenital equino-varus is due essentially to an alteration in the shape of all the bones of the foot. The tilting forward of the astragalus, carrying with it the os calcis, produces a plantar flexion of the foot at the ankle-joint. The inward twist of the neck of the os calcis and of the astragalus, causing an inward deviation of the anterior articular facets of the mid-tarsal joint, combined with the adduction and rotation of the scaphoid and cuboid, produces the varus position of

Congenital Equino-Varus. Frozen section, vertical, in the plane of the malleoli at about the level of the mid-tarsal joint, through a right congenital club-foot at birth. surfaces of the os calcis and astragalus, which are uncovered and fail to articulate with the proper bones, lose their cartilage, which may be replaced by fibrous tissue or bone. This renders late reposition of the foot difficult. The ligaments bind the anterior tarsal bones more firmly in their abnormal positions. The marked inward direction of the anterior facet of the astragalus prevents forcible correction of the scaphoid or tends to cause recurrence of the deformity, if reposition is possible. The inward direction of the anterior facet of the os calcis prevents reduction of the cuboid, or tends to cause recurrence if reduction is possible. The contraction of the plantar fascia is more marked and the contraction of the anterior and posterior tibial tendon is extreme. Firm ligaments bind the scaphoid to the internal malleolus, the cuboid to the inner side of the os calcis, and the posterior surface of the astragalus to the external malleolus. The skin over the point of pressure of the foot upon the ground thickens, and large bursæ may form.

REDUCTION OF THE DEFORMITY.

To reduce the deformity it is evident that each step of the deformity must be corrected, that is, the contraction of the sole of the foot, the inward rotary deviation of the anterior part of the foot at the mid-tarsal joint; the inward obliquity of the mid-tarsal joint, the inward deviation of the astragalus and os calcis, and the plantar-flexion of the foot at the ankle-joint.

In infantile and non-resistant cases division of the plantar fascia will correct the contraction of the sole. Forcible reposition, with, if necessary, division of the anterior and posterior tibial tendons, and of the calcaneo-scapoid and calcaneo-cuboid ligaments, will cor-

cis. From the anatomy it is evident that an operation which neglects to correct the inward obliquity of the mid-tarsal joint and the inward deviation of the astragalus and os calcis must be faulty, and liable to be followed by a recurrence of the deformity. A correction of the deformity of the anterior part of the foot alone will leave a re-entrant angle between the head of the os calcis and the cuboid, and is tolerably certain to be followed by a relapse.

The rational treatment of the deformity must depend upon a recognition of the essential changes that produce it. Division of the plantar fascia will correct the contraction of the sole. Division of the anterior tibial tendon, the calcaneo-scapoid ligament, the calcaneo-cuboid ligament, possibly the posterior tibial

Congenital Equino-Varus. Frozen section, vertical, in the plane of the malleoli, about one-quarter of an inch posterior to the section in Fig. 5. Shows the compression of the astragalus; the obliquity of the os calcis; the altered position inward of the cuboid; and the relations of the cuneiforms.

rect the rotation and varus. Division of the tendo-Achillis and forcible reposition will correct the plantar flexion and inward deviation of the astragalus and os calcis. On account of the cartilaginous, yielding structure of the bones, division of tendons, forcible reposition of the foot, and retention of the foot in an overcorrected position will generally suffice, because the distorted bones conform to the corrected position.

In adult and resistant cases the bones are hard, no longer cartilaginous; the ligaments are very firm; and all steps of the deformity are accentuated. To correct these obstinate cases many operations have been recommended; for example, removal of the cuboid; of the astragalus; of the astragalus, cuboid and scaphoid; of the astragalus and external malleolus; division of all internal soft parts down to the bone; wedge-shaped osteotomy of the outer side of the os calcis; and, finally, osteotomy of the neck of the astragalus and of the neck of the os cal-

Congenital Equino-Varus. Frozen section, vertical, in the plane of the malleoli, about one-quarter of an inch posterior to the section in Fig. 6. Shows the os calcis cut obliquely; the altered position inward of the cuboid; the internal cuneiform; and the heads of four metatarsals.

tendon, with osteotomy of the neck of the astragalus, and of the neck of the os calcis, followed by forcible reposition, will correct the varus and rotation at the mid-tarsal joint. Division of the tendo-Achillis, with forcible reposition, will correct the plantar flexion at the ankle-joint, and the inward deviation of the astragalus and os calcis.

SUMMARY.

The deformity in cases of congenital club-foot is due to alterations in the shape of all the bones of the foot, accompanied by contraction of certain tendons and ligaments. The chief deformity is at the "mid-tarsal" joint, and is due to an inward deviation of the anterior articular facets of the os calcis and astragalus. A failure to correct this obliquity is a failure to correct the deformity. In resistant cases the obliquity can be corrected best by an osteotomy of the neck of the os calcis and of the astragalus, followed by forcible reposition of the foot.

AIR-EMBOLISM, WITH REPORT OF CASES, CLINICAL AND EXPERIMENTAL.¹

BY JAY PERKINS, M.D.,

Medical Examiner, District No. 10, Providence County, R. I., Pathologist Rhode Island Hospital.

THIS subject of air-embolism, is one of peculiar interest because of the sudden onset of dangerous symptoms. Sudden death upon the operating-table strikes terror to the heart of any operator. To have a patient die suddenly during or after confinement is unfortunate for all concerned; but more impressive and more ruinous than either of these is it to have a patient die suddenly while a physician or other person is secretly performing a criminal operation or abortion.

Deaths under any of these circumstances may, and a number of times have, taken place in consequence of the entrance of air into the veins. The first recorded case of death thus caused was reported by Beauchêne in 1818. Since then there have been many cases reported by different physicians, especially in England, France and America. Yet the cases are sufficiently rare so that the average practitioner knows little or nothing about the accident. I find that many are wholly ignorant of the fact that such a form of death ever occurs. Were it more generally known and looked for, probably many more cases would be reported. It is hard to establish this as an absolute cause of death unless an autopsy is held, and that before putrefaction has set in. And even then it may be overlooked unless the pathologist has it in mind and looks especially for it.

Cases have been reported where severe symptoms or death have followed the entrance of air through the jugular subclavian, axillary, anterior thoracic, facial, femoral and uterine veins, and the sinuses of the skull; and many experiments have been made demonstrating the action of air in the circulation. The most thorough and complete experiments recorded are those by Senn, as published in the "Transactions of the American Surgical Association" for 1885.

For the accidental admission of air into the circulation to take place, it is necessary that a vein should become canalized. For ordinarily when a vein is cut it collapses and closes as by a valve, permitting blood to flow out but not admitting anything to pass in. This closure, may, however, be prevented by a partial division of the vein while it is on the stretch; by the vein being pulled upon from all sides, as in the neck and axilla when the muscles of respiration are in action; or by the vein being enclosed in and attached to firm tissues, as in bone, or the uterine tissue when the uterine muscle is relaxed, the uterus being pregnant.

The part of this subject to which I wish especially to call your attention and ask for your discussion is the entrance of air through the uterine veins.

In "Braithwait's Retrospect" for 1851 there is a record of three deaths from this cause, the authority being Dr. Lever. All of the cases were multiparæ, labor not long, placenta thrown off without assistance, and an inert stage of the uterus with hemorrhage followed. Forceful compression over the uterus with the hand was used. When the hand was removed a rushing sound was heard and all of the patients died speedily. In two of these cases an autopsy was held

before any decomposition had begun, the third was beginning to decompose. There was air in the vessels of all three.

Heckford² reports the case of a patient forty-three years of age, eighteenth confinement. After a few strong pains a living child was expelled and the mother expired. Those present said: "Death was instantaneous and without the least struggling; she turned on her back and was dead." No hemorrhage had taken place, and the placenta had not been interfered with. Post-mortem, air was found in the heart and vessels. Air bubbled from the vessels as the different viscera were cut.

Cordwint.³ Mrs. W., married. Full-term, strong, expulsive pains became urgent, and patient remained standing. Child born, falling to the floor and dragging the placenta with it. Almost immediately a gurgling sound was heard by the attendants. Patient remained standing about one minute, holding to a bed-post. She then said: "I can't see, I feel faint. Lay me on the bed." And she died instantly. At the autopsy a portion of the wall of the fundus of the uterus was more puffy than the rest, and on section air escaped. Air was in the heart and vessels.

Dr. Cheever.⁴ Tumor of uterus, thought to be cystic, of ovary. Aspirated; no fluid, aspirator working all right. Needle withdrawn. Phenomena of air-embolism at once ensued. Artificial respiration was used, and hastened the result by sucking in more air. Autopsy by Dr. Draper, who said that the uterine wall outside of the tumor was very much thinned, while the sinuses were very much developed. Where the air entered near the left cornu the tumor had been separated somewhat, and there was some reddening of the part by infiltrated blood. There was a distinct solution of continuity, of the size of a silver quarter, between the tumor and the uterine wall which could not have been made by the finger, as Dr. Cheever had supposed. Air was in the heart and vessels.

May.⁵ Mrs. T., thirty-eight to forty; sixth child, male, May 7, 1852, 8 A. M. Severe after-pains; great oppression about the chest; feeling of sinking and exhaustion and extreme restlessness; no hemorrhage. Died at 2 o'clock in the afternoon. Autopsy the same evening. Air in the heart and blood-vessels.

Mrs. E., twenty-eight, third child. Natural labor. While doing household work, eighth day after labor, was taken suddenly ill, and died at once. Autopsy the following day. Bloody froth in the right side of the heart, etc. Uterus normal size for eighth day. No decomposition.

Swinburne.⁶ Miss M. A. S., twenty-three. Three attempts were made, from day to day, to rupture the membranes with some blunt instrument, without success, by a professional female abortionist. Dr. Carr was called suddenly. Woman had fainted. Keeper of house said she had used only an india rubber, and showed a gutta-percha catheter which she said was what she had used. Post-mortem fourteen hours after death. Deceased was five months pregnant. On the right latero-posterior surface of the uterus the membranes and part of the placenta were separated

¹ Medical Times and Gazette, February 9, 1867.² St. George's Hospital Reports, 1871-72.³ Boston Medical and Surgical Journal, November 29, 1883.⁴ British Medical Journal, June 6, 1857.⁵ Medical and Surgical Reporter, Philadelphia, April 23, 1859.⁶ Read before the Rhode Island Medico-Legal Society, June, 1896.

from the uterine wall. Beneath the free border of the placenta were several small coagula. There was found (1) slight softening of the tissues, (2) several abrasions evidently not natural, (3) a perforation communicating directly with the uterine sinuses, about two inches from the cervix. Air was found in the heart and vessels.

Hekton.⁷ Patient, nineteen, married seven weeks, four months pregnant, went to her room for the alleged purpose of changing her dress. In a few minutes a fall was heard, and the woman was found to be dead. A Davidson's syringe, a chamber vessel and a basin of cold water were arranged as if she had commenced to take a douche. She was found dead twelve minutes from the time she went to her room. The autopsy showed air in heart and vessels. At the inferior border of the placenta there was a separation to the extent of three-fourths of an inch. Many ruptured sinuses were seen.

M. De Paul.⁸ Rickety woman, twenty-two. Twice delivered by cephalotripsy, and one premature delivery. On fourth pregnancy M. De Paul decided to bring on labor at seven and one-half months. Douche administered on two occasions without success. On the third time air was seen to come out of the vagina with the water, but the apparatus was working well, apparently, and the douche was continued. M. De Paul asked the patient to arise and walk about the room; but when she tried to arise she turned pale and fell dead. Cæsarean section. Uterus pale pink; bloody froth from sinuses of uterus on section, and bubbles of air escaped from between the membranes and the wall of the uterus. No autopsy.

Hitchcock,⁹ two cases.

CASE I. Mrs. LaFargue, four to five months pregnant. Abortifacient blew into catheter while withdrawing it. Instant death. Conflicting testimony at trial as to post-mortem appearances, but air was in the heart and vessels.

CASE II. L. R. J., twenty-one, single, between seven and eight months pregnant, died suddenly in a physician's office. The physician claimed that he merely made a digital vaginal examination and the patient fell back in a faint. Autopsy eighteen hours after death. Body was kept in a cool room on a marble slab, and was well preserved. Some blood about the external genitals and clothing. Heart and veins distended with air. Membranes unruptured, but separated from the uterine wall to a considerable extent, opening up the uterine sinuses.

The six cases following were taken from the *American Journal Medical Sciences*, October, 1857.

CASE I. In 1841 Dr. Bessems attended a labor with which there was hemorrhage with retention of the placenta. On the fourth day after her confinement, while water was being thrown into her uterus she suddenly exclaimed that she was suffocating, and she died in three minutes. Air was found in the heart and veins.

CASE II. M. Lionet, of Corbeil, attended a woman aged twenty-seven. Labor natural; no hemorrhage. She soon, however, became faint, breathed with difficulty, and expired five hours after delivery. Air was found in the heart and cerebral veins.

CASE III. Dr. Wintrich, in 1848, published a case

of rapid death after parturition. Convulsive movements and suffocation followed the expulsion of the infant and partial separation of the placenta. Air was found in the venous system.

CASE IV. Professor Simpson mentions a case in which death occurred a few hours after delivery, accompanied with hemorrhage and alternate relaxations and contractions of the uterus. Air was found to have entered through the uterine veins.

CASE V. In 1850 Mr. Berry, of Birmingham, attended a primipara aged twenty-two. But little hemorrhage. She did well for six hours, and then had difficulty of breathing and faintness, and expired in less than an hour. Air was found in the heart, and the uterine veins were patulous.

CASE VI. Case of Mr. Taylor. Mrs. —, thirty, third child. Mr. T. was in the act of introducing a catheter to draw her urine, when a severe pain occurred. Three-fourths of a pint of liquor amnii was discharged. The woman suddenly exclaimed, "Oh, how faint I feel!" was convulsed for a moment, and then expired. The heart was distended with air.

Professor Oppolzer¹⁰ relates a case of uterine cancer, death occurring from the entrance of air. The autopsy showed air or frothy blood in the heart and veins.

Davidson¹¹ relates the case of a Hindoo woman. Labor normal; placenta came away all right; no post-partum hemorrhage. About three-quarters of an hour later the woman died, without any apparent cause. At the post-mortem, two hours later, the uterus was found empty, with large and somewhat distended veins, air and frothy blood in the right side of the heart.

Bram (quoted by Senn in his article on air-embolism) gives two fatal cases from the introduction of air into the uterine veins. The uterine douche was used, in one case to produce an abortion, and in the other after the delivery of twins. Both patients died in a short time. Autopsy showed air in the heart and veins.

Senn also mentions a case of Olshausen's, that of Mrs. —, twenty-nine, second child. Labor was lingering, and the midwife forced water into the vagina gently with a pump. A third injection was used. After eight minutes' use the patient began to complain of oppression. The tube was withdrawn. The patient arose in bed, but immediately fell back senseless, and died in less than a minute under convulsive respiratory movements and distortion of the face. On touching the body widespread crepitation was felt. Autopsy eight hours after death. A little frothy blood was in the right heart and a large amount of air in the veins. A small portion of the placenta was detached from the uterus.

Draper¹² reports two cases:

CASE I. M. A. F., twenty-eight, married, was found dead in a house of ill-repute. Autopsy twenty-three hours after the assumed time of death, the body having been kept cool. The uterus contained a fetus of about three months; membranes unbroken. Placenta of about the size of a silver half-dollar. There was air in the uterus. Light pressure on the placenta gave the characteristic crepitan sign of air between it and the uterine wall. The right cavities of the heart

⁷ North American Practitioner, March, 1891.

¹² Boston Medical and Surgical Journal, January 1, 1883.

and the vessels distended with air. No lesion of the external genitals or vagina. Just within the external os the mucous membrane was reddened over an annular area two or three lines wide; and just above the internal os and at the lowest part of the ovum there was an ecchymosed patch or streak half an inch long and one-eighth of an inch wide; at the right and most discolored end of this bruise there was a rent of the decidua admitting freely to the placental attachment. In Dr. Draper's opinion this abrasion was made by some instrument like a catheter, which instead of rupturing the membranes had glanced aside and torn up the decidua layers, though there was no distinct separation of the placenta from the uterus.

CASE II. L. R. J., twenty-one, single, between seven and eight months pregnant, died suddenly in a physician's office. The physician claimed that he merely made a digital vaginal examination. The patient suddenly threw her hands above her head and fell back with a low moan or cry, then had a convulsion with some frothing at the mouth, and became unconscious. This was one of his stories, and the other was that she fell back in a faint.

Autopsy eighteen hours after death. Body kept in a cool room on a marble slab, and well preserved. Some blood about the external genitals and clothing. Heart and veins distended with air. Membranes unruptured, but separated from the uterine wall to a considerable extent, opening up the uterine sinuses.

The same author¹⁸ reports: A. H. J., thirty, married, multipara, five months pregnant. Had been warned by a physician that she ought not to have any more children because of lateral curvature of the spine. She went to Mrs. X., an abortionist, and went into an inner room with her, leaving her sister in the waiting-room. In a few minutes the sister, hearing some confusion in the inner room, invaded its privacy, and saw the patient flat on her back on the floor. There was no sign of life excepting a little gurgling noise in her throat. On the carpet at the patient's feet was "a silver thing about five inches long and of the size of a lead pencil." Autopsy eighteen hours after woman's death, the body having been kept in a cold room during the last twelve hours of that period. The right side of the heart was distended with air and frothy blood; the left ventricle was firmly contracted.

(To be continued.)

Clinical Department.

NOTES OF A CASE OF EXTRA-UTERINE GESTATION; RUPTURE OF THE SAC; OPERATION AND RECOVERY.¹

BY S. E. WYMAN, M.D., CAMBRIDGE, MASS.

THE comparative rarity of cases of ectopic gestation; the obscurity of the symptoms before rupture, with the consequent difficulties of diagnosis; the extreme gravity of the prognosis after rupture has taken place; and the triumphs of modern aseptic abdominal surgery render extremely interesting the history of this case which it is my privilege to report to you to-night.

¹ Read before the Cambridge Medical Improvement Society, December, 1895.

¹⁸ Boston Medical and Surgical Journal, April 30, 1896.

Statistics as to the frequency of cases of this condition are necessarily unreliable, since so many are unrecognized, death from rupture of the sac being attributed to other causes, for example, peritonitis, hematocele, abdominal tumor, etc. But, where access can be had to the records of hospitals, in which autopsies are uniformly made, a nearer approximation to the truth can be reached. Such records are to be found in connection with the hospitals of Vienna; and "Bandl" declares that out of 60,000 gynecological and obstetric cases received during seven years at the clinics of Carl Braun and Späth, in Vienna, there were five cases of extra-uterine pregnancy."

Thomas² writes: "During the past twenty years I have personally examined and treated thirty-three cases. . . . However, the great majority of my cases were seen in consultation with other physicians."

These statistics, however, seem like ancient history — coming from books published in 1888, a date since which such rapid strides have been made in abdominal surgery — and, while valuable, are not a sure guide as to the frequency of cases of this condition; of which fact we are further apprised by the cases reported before the Boston and other medical societies and published in the current medical journals. Certainly, these cases are more often recognized and successfully treated to-day than formerly.

The difficulties of diagnosis are often great, the symptoms being obscure and not of such import as to alarm the patient as to her condition.

Not infrequently there appears, in the course of a supposed normal pregnancy, a bloody flow of greater or less persistency, with occasional gushes of blood; paroxysmal pelvic pain, extending down the thighs; and sometimes symptoms of abortion, with expulsion of pieces of decidua, but without expulsion of the fetus. An hematocele may be formed, the mass of blood become absorbed, and the case thus have a fortunate issue.

If the fetus is already of considerable size, the bones may become encapsulated and thus remain quiescent; or they may, by their irritation, give rise to an abscess and be discharged either through the abdominal walls or through the neighboring viscera — intestines, bladder or vagina.

In other cases, however, the first symptoms are those of rupture of the sac, with severe agonizing pain and evidences of intra-abdominal hemorrhage. It is to the last class that the case I have to report belongs.

On the morning of the 12th of August, 1895, I was called at three o'clock to see Mrs. A. G. The patient, thirty years of age, was born in England, and is the mother of a daughter eleven years of age. No miscarriages. Menstruation never regular, often painful, and often absent for three months.

In October, 1894, the uterus was curetted and an Alexander operation performed for malposition of the uterus. She had been in excellent health after the operation, indulging in the pleasure of bicycling. Menstruated last in April, 1895. There had been no symptoms of pregnancy, with the exception of slight pains in her breasts and the occasional escape of moisture from her nipples. Having no idea that she could be pregnant, she had been taking iron for the amenorrhea.

On the morning of August 10th she was taken un-

² Hart and Barbour: Gynecology.

³ American System of Gynecology, vol. II, p. 178.

well, the flow being scanty and attended with some pain. While engaged in her household duties, she was seized with severe, sudden pain, which doubled her up and compelled her to spend the remainder of the day on a couch. She had a feeling of faintness whenever she raised her head from the pillow. She spent the forenoon of August 11th on her bed, but sat up during the afternoon. Sometime after two o'clock of the morning of August 12th she was seized with very severe agonizing pain in the abdomen, accompanied by the feeling of impending death. Two tablets of morphia (probably one-quarter grain) were given by her husband without any relief, and aid was sought.

When seen at 3.15 A. M. (it was a warm morning) the patient was lying under heavy bed-clothes (two blankets and a thick quilt), but cold. Her body was covered with clammy perspiration, and she complained of exquisite pain. Countenance anxious; face and lips blanched; pupils large; pulse weak, but 55 (a rate wholly inexplicable to me then and now, but verified by auscultation of the cardiac sounds); abdomen tender to slightest palpation, especially to the right and below the umbilicus; thirst prominent; profound collapse.

One-eighth of a grain of morphia subcutaneously at 3.30, and artificial heat. At 4 A. M. she seemed at the point of death. Stimulants were administered; but whether any absorption took place is doubtful, as she vomited at 4.45.

At 5 o'clock Dr. Swan saw the patient in consultation. The symptoms were not so alarming; the pulse-rate was slow, such as to seem to Dr. Swan not to indicate hemorrhage. At 5.45 the patient was easier. Rectal and vaginal examination negative. At 10 o'clock Dr. Swan saw her with me a second time, when the gravity of her condition was more pronounced. Pulse 120, temperature 100.4° in axilla. Abdomen tympanitic, moved with respiration, tender on pressure, with dullness in the right iliac region.

At 12.30 she was seen by Dr. A. T. Cabot, in consultation. Pulse 128, temperature 99° in axilla. Face anxious, respiration sighing, skin bathed with clammy perspiration.

After consultation, a diagnosis was made of probable rupture of an extra-uterine gestation, and an immediate operation advised.

Corrosive pack (1 to 4,000) to abdomen. At 3.30 P. M. preparations were completed for laparotomy. An enema of whiskey, one ounce, and tincture digitalis, one drachm, given, and patient etherized at 3 P. M., when Dr. A. T. Cabot operated, Dr. Balch and Dr. Swan assisting. Pulse 148. A median incision was made through the abdominal walls, the tissues of which contained but little blood. When the peritoneal cavity was opened, dark blood flowed out, containing clots, some of which were quite firm and comparatively old. The posterior cul-de-sac was full of large clots. The fetus was discharged with the liquid blood, but was found and verified.

Upon examination it was found that the hemorrhage came from the right tube at the fimbriated extremity, where placental tissue could be seen; the right ovary was cystic. The tube was clamped, ligated, and the right ovary removed. The peritoneal cavity was freed of blood and clots by sponging, and the edges of the incision united by deep and superficial sutures. At 4 P. M. the patient was in bed with its foot raised and artificial heat applied. Pulse 140.

The patient rallied quickly without any vomiting; but as she complained of considerable pain and was restless, a rectal tube was passed, allowing the escape of considerable flatus, the bladder was catheterized and urine (six ounces) drawn. A subcutaneous injection of one-eighth of a grain of morphia was given at 7 P. M.

Patient had an excellent night's sleep, and her recovery was rapid and uneventful. Urine passed naturally within twelve hours, and the bowels moved fifty hours after operation, from the use of salines. On the third day after the operation there was a bright vaginal discharge and a piece of deciduous membrane on the napkin, which I regret was not carefully examined. On the ninth day the sutures were removed and the wound dressed with crêpe lisse and collodion. On the twentieth day the patient sat up in bed for a short time. In four weeks after the operation menstruation was re-established.

A CASE OF WEB-FINGERS, ASSOCIATED WITH CURIOUS ANOMALIES OF THE PHALANGES, METACARPAL BONES AND FINGER-NAILS; WITH SKIAGRAM.

BY F. B. LUND, M.D.,

Surgeon to Out-Patients, Boston City Hospital.

M. F., a girl of eighteen years, was referred to me at the Outpatient Department of the Boston City Hospital, by Dr. J. Orne Green, for advice with regard to operation for the separation of web-fingers. Operation had been previously considered, and advised against; but it was thought that the x-rays might perhaps give some further information with regard to the advisability of operation than could be secured by the ordinary methods of examination. Although the skiagram, which was kindly taken by Dr. F. H. Williams simply confirmed the previous decision with regard to the advisability of operation, it at the same time revealed such a curious condition of the bones of the hand as to render the case one of considerable interest.

The fingers of the left hand, which was smaller than the right, were completely webbed, down to the tips of the third phalanges, and all the phalanges were of equal length, so that, as is evident from the skiagram here reproduced, the ends of the fingers formed a straight line.

Instead of a separate finger-nail for each phalanx, one continuous nail extended across the whole width of the flipper-like hand, the line of demarcation between the fingers being marked merely by a slight but distinct groove. The phalanges were so crowded together that the hand was narrow and tapering. Flexion and extension of the phalanges was normal, as were all movements of the thumb. The hand was therefore of a good deal of service to its owner, and might be very well compared to a hand on which a mitten was worn. It was about two-thirds the size of the right hand, which was normal in every respect.

The skiagram shows the following curious condition: The second phalanx of the forefinger is rudimentary and is dislocated backward. The terminal phalanx of the forefinger is bifid, and the inner portion is ankylosed to the terminal phalanx of the middle finger. The metacarpal and first phalanx of the

forefinger are much longer and stronger than those of the other fingers, and there is a wide space between the first and second metacarpo-phalangeal joints. The middle finger shows a rudimentary metacarpal bone, about half the length of the others, and the normal number and relation of the phalanges. In the ring finger the second phalanx is absent, and in the little finger it is rudimentary. The phalanges and metacarpal bones of the three inner fingers are crowded so closely together that the bones touch each other at the joints.

Although since the use of the x-rays in diagnosis large numbers of anomalies of the phalanges have been brought to light, the bones of the hand here de-

picted are as "irregularly irregular" as any that I have seen published.

The skiagram showed conclusively that all that could possibly be done in the way of operation, would be perhaps to free the fore from the middle finger, and it was thought that even if this were accomplished, it might be impossible at her age to secure independent action of the muscles of that finger. There is little doubt that a dissection of the hand and forearm would show muscular anomalies, for example, absent or rudimentary interossei, etc.

In this case there was no family history of similar deformity, such as was present in the case shown in the JOURNAL of February 20, 1896, and in two of the cases quoted by Dr. Thomas Dwight in the editorial article on "Anomalies of the Phalanges" in the same number.

Medical Progress.

REPORT ON ORTHOPEDIC SURGERY.

BY E. R. BRADFORD, M.D. AND E. G. BRACKETT, M.D., BOSTON.

CURVATURE OF THE AORTA IN POTT'S DISEASE.

BOUCHACOURT,¹ in a bulletin of the Anatomical Society of Paris, has described the deviation of the aorta in dorsal lumbar Pott's disease, in the patient of Kirmisson, fourteen years of age. The same deformity has been described by Professor Dwight in the *American Journal of the Medical Sciences*, January, 1897. It consists of a curvature of the aorta independent of the curve of the spine. The spinal column was much shortened. The aorta was of the normal length, and not finding room along the column, was forced to wind itself irregularly from side to side.

PRIMARY ACUTE OSTEOMYELITIS OF THE SPINE.

Hahn² has collected a number of cases of osteomyelitis of the spinal column. The diagnosis is not easily made, and the prognosis is doubtful. Treatment consists of an early and thorough opening of the abscess and the prevention of the deformity by the treatment usual to tubercular disease.

G. H. Makins and F. C. Abbot have contributed an excellent article on this subject to the *Annals of Surgery*, May, 1896, with an analysis of 21 cases. In 11 cases the spinal cord was involved.

Müller³ describes a case of osteomyelitis of the spinal column, to which he adds the history of seven other cases. His patient was twelve years old; was seized with fever, headache, pain in the back, and a motor and sensory paralysis, with paralysis of the bladder, which he considered to be a case of Landry's paralysis, but which soon developed an abscess in the thoracic region, which was opened and showed a sequestrum in the thoracic vertebra, as well as a collection of pus in the spinal canal. This was followed by edema of the lungs and death. An osteomyelitis of two lumbar, three dorsal and a cervical vertebra was discovered.

The diagnosis between this and a tubercular process is based, according to Müller, on a very acute curve and the early appearance of paralysis.

ANCHYLOSIS OF THE ATLAS.

Gelsam⁴ reports three cases of ankylosis of the atlas. He has only been able to collect three of these cases, although Lombroso and Paoli claim a greater frequency. They present no clear symptoms during life. In one case the ankylosis was reported as a result of rheumatic inflammation; in the other two it seemed to be a defect of development. Gelsam considered in one instance the result to be due to an inflammation following a blow. Haun reports a case of acute osteomyelitis of the vertebra similar to that of Müller.

COSTO-TRANSVERSECTOMIE.

Menard⁵ reports the results of operation on cases of paralysis from tubercular spinal abscess by an opening through the posterior part of the trunk. The opening was made by the resection of a transverse process of the infected vertebra and the adjacent rib. The

operation was found not to be difficult, and the result was satisfactory. The cases all showed improvement, the paralysis disappearing. In all six cases the operation was on the right side.

ARRANGEMENTS FOR THE TREATMENT OF STIFFNESS OF THE FINGERS.

Krukenberg⁶ has devised an ingenious and simple arrangement to correct stiffness of the fingers so frequently seen after fracture. It consists of a glove of the ordinary stout leather, dogskin or kid, which is furnished with strings attached to the tips of the fingers and passing through small rings at the wrist. At the ends of these strings weights of from one to three pounds are fastened. If the hand is held upward for a quarter of an hour, the weight exerts a pull upon the fingers bending them toward the palm.

Dolega⁷ recommends a somewhat similar plan, with the addition of longer strings which pass through attachments at the bend of the elbow and are fastened to the undershirt. On straightening the arm a pull on the fingers is exerted.

TREATMENT OF CONTRACTION OF THE SHOULDER.

Kaun⁸ describes this affection, which is, as is well known, obstinate in treatment. The contraction is almost always in the direction of adduction, owing to the leverage of the weight of the arm; forward and back motion is usually made readily, but pure abduction is limited. *Brisement forcé* is frequently employed, but the benefit is not always evident, and it is rejected by some surgeons. The writer recommends mechanical gymnastics, using an apparatus which is a modification of that used by Zander. It consists of a place to rest the arm, balanced by a weight attached to a longer arm. The shoulder is kept down in place by means of pressure, and motion is easily graduated by means of a shifting weight.

CONGENITAL ELEVATION OF THE SHOULDER.⁹

In 1891 Sprengel called attention to a deformity which had hitherto not been described, namely, a congenital elevated position of the shoulder-blade. Kolliker, Schlange, Hoffa, Kirmisson and others have described similar cases. The affection is a congenital deformity of the shoulder-blade. In the way of treatment nothing can be done with the exception of an operation, which in certain cases apparently is of help. Division of the shortened muscles is not beneficial, and has been rejected by some writers. Hoffa, in addition to dividing the muscles, chiselled off a portion of the corner of the shoulder-blade; the scapulæ were pulled down and kept in an altered position by means of an elastic pull attached to a scoliotic corset.

THE LOCAL USE OF HYDROCHLORIC ACID IN BONE NECROSIS OF TUBERCULAR ORIGIN.

Dr. Jerome H. Waterman¹⁰ reports the results of the use of strong hydrochloric acid used locally on bone necrosis in eight cases. This treatment was used, on the theory that the acid dissolved the earthy salts in healthy bone without injury to the animal matter of the bone, and that in this way the disease would be more directly attacked.

The acid was applied, after a thorough cleansing of the wound by sterile water, by the injection of a few minims through a glass pipette.

Eight cases are reported, of which marked benefit was found to result in four, and improvement in two others. He gives the following conclusions:

- (1) No evil effects have resulted from its use.
- (2) The use of the acid in its concentrated form is preferable.
- (3) When the area of necrosis is extensive, operative methods are advised.
- (4) Its action is limited to the necrosed area; whereas curetting may remove both diseased and healthy bone.
- (5) By the disintegration of the dead bone the newly-formed tissue has a better opportunity for its more rapid development.

TREATMENT OF WHITE SWELLING OF THE KNEE.

Calot F. and J. Decherf,¹¹ consider the question of operative treatment of white swelling as compared in adults and children. The natural course of the disease is different essentially, varying with the age, which seems to be the result of the resisting power of the individual. In children there is a decided tendency toward spontaneous cure. First, in regard to the treatment of this condition in adults, the chances for cure by conservative methods alone is much less; the time required is much greater, and frequently the surgeon must be guided by the consideration of the economy of time. Second, that the danger of general tubercular affection is not great with a child, but is so with adults; and one must consider the advantage of immediately removing a tubercular focus before it becomes a source of danger for infection. In such cases, when the operation is performed early and the extension of the disease is not great, the amount of shortening is slight. If, however, the lesions have extended, the amount that is necessary to completely extirpate the disease results in a great amount of shortening of the limb. In such cases, when this is necessary and when the general condition is not good, and if there is a reason to suspect invasion of the lungs, it is better to amputate rather than to excise. The resection in these cases frequently gives good results, but the patient more often dies from this than from the amputation.

RICE BODIES IN TUBERCULOUS SYNOVITIS.

Dr. Heinrich Riese¹² illustrates his article with plates and drawings, and gives minute details with regard to the preparation and staining of the specimens. He concludes that these rice bodies, both in the tendon sheath and in the bursa, are derived from a fibrin clot, one group springing from the clot grows in the synovial fluid, another working its way into the tissue which forms the wall about the synovial cavity, and that in both places they became organized.

OSTEOMYELITIS.

Canor¹³ in a contribution upon osteomyelitis with reference to immunity, gives the following conclusions:

The experiments were performed upon rabbits in four groups: (1) The production of osteomyelitis through the injection of staphylococci into a blood-vessel. (2) Through the injection of other micro-or-

ganisms. (3) The production of osteomyelitis through the gastro-intestinal canal. (4) Inoculation.

Tables are given showing the conditions under which the experiments were carried out as to temperature, culture, preparations, amounts given and manner in which it was done. The author admits that the investigations are not conclusive, but that they are encouraging, in that they show that he is working in the right direction.

TRAUMATIC INFLAMMATION OF THE BURSE OVER THE GREAT TROCHANTER.

Thiem¹⁴ claims that chronic inflammation of the gluteal trochanteric bursa is not so rare from injury; for a diagnosis it is especially important to notice that limitation of motion is in the direction of adduction and internal rotation. Contusion of the trochanter combined with a quick turn of the body with the limb fixed is apt to cause this injury.

OPERATIVE TREATMENT OF PARALYTIC CLUB-FOOT.

Kirmisson¹⁵ reports a number of cases where arthrodesis was performed on the different joints in the foot. He criticises the plan of limiting the operation to the tibio-tarsal joint, as it has been the experience that many of these cases develop later an abnormal mobility of the mid-tarsal joint, which impairs to a great extent the early result. Saunter, to avoid this, has opened the tibio-tarsal articulation from behind along the border under the tendo-Achillis, making an incision ten centimetres long, and cutting the tendo-Achillis, in this way obtaining access to the ankle-joint. Three operations by this method are claimed by him to have given good results. Karewski considers that it is necessary to extend the arthrodesis to the astragalo-calcaneus articulation as well. Besides 23 cases, 18 of which were paralytic, he performed arthrodesis on the calcaneo-astragaloid articulation. Sometimes it is necessary to operate on the small articulations of the foot. He uses an incision on the interior part of the foot, which allows one to open the tibio-tarsal joint. Kirmisson also considers that the transverse anterior incision is convenient; it is better to avoid this anterior part of the foot if necessary, on account of the tendons and nerves, although the tendons can be sutured. It is unfortunate if the nerves are severed. He uses an incision small enough to allow the passage of an osteotome at the level of the external malleolus. The object of this is to allow one to completely invert the foot, and in this way to expose freely to view the two surfaces of the tibia-tarsal articulation, after which an L-shape incision is carried around the internal malleolus; the periosteum is detached and the ligaments divided, by which one can completely subluxate the foot on the leg; the cartilage is removed by a gouge; and the operation is completed by joining the two articular surfaces by pegs of bone, two to three millimetres in diameter and five centimetres long. It is naturally of great importance that these pegs should be absolutely aseptic, and hence the practice of boiling these in carbolic acid, after which they are kept in a strong solution until the moment of their use. By these precautions they have never observed any bad results from their use. Fifteen cases are reported: in 11 arthrodesis of the tibio-tarsal joint was performed; nine times of this joint alone;

twice combined with the mid-tarsal articulation, and twice with the astragalo-scapoid; arthrodesis of the whole mid-tarsal joint two times. Of the 15 operations, in 11 these pegs were used, and the presence of an ivory peg gave no inconvenience; the functional results have been satisfactory.

INFANTILE PARALYSIS.

Sighicelli¹⁶ recommends the use of electricity in infantile paralysis after the limb has been made bloodless by an elastic bandage. He reports four cases where marked improvement was observed after such treatment, even in one case where the paralysis had persisted for four years. His argument in favor of this method of treatment is that if the limb is deprived of its blood, it becomes a more homogeneous medium for the electrical current, and for that reason a smaller amount of the electrical power is lost. There is a certain advantage in the artificial anemia in that the sensation is diminished, and for that reason a stronger stream of electricity can be used.

CLUB-FOOT SHOE.

Nabel¹⁷ writes upon the fixation of the heel in club-foot shoes, preferring the method recommended by Schaffer, modifying it, however, and adapting it to a shoe in such a way that all buckles are avoided, straps being tied to counter-straps inside.

CONCERNING FOOT-JOINT AND TARSAL TUBERCULOSIS.

E. Spengler¹⁸ treats the subject from all possible points of view, and tabulated results are carefully worked out from a large mass of clinical material. As to age, the largest number of cases fell between twenty and thirty. That due to direct hereditary influence was found to be 25 per cent., while in 36 per cent. there was probably no tuberculosis in the family history. Among the statistics of exciting causes, distortion and spontaneous beginning had the largest percentages.

Primary tubercular-ostitis, and that secondary to other forms, are discussed at length, as also when complicated with other affections.

In a comparison as to the bones most frequently attacked, the talus, calcaneus, cuboid, and tibia held the highest ranks.

As to the indication for a operation, the author holds to general surgical rules; contraindications, in a young patient suffering with any form of heart trouble, also in cases of advanced age. In the radical treatment, results are shown under the heads of arthrotomy, arthrectomy, excision and resection, exarticulation, amputation, etc. Those in conservative treatment are tabulated under expective, injection, incision, ignipuncture.

After exhaustively setting forth the advantages and disadvantages of each, the writer concludes that every method is good and yields good results, provided it is chosen to fit the case, but that every method is not good for every case.

FLAT-FOOT. — HAMMER-TOE.

Ranneft¹⁹ reports an unusual deformity which was described by Nicoladoni under the title of hammer-toe

¹⁴ Zeitschrift f. orthopädische Chirurgie, Band iv, Heft 2, p. 452.

¹⁵ Revue d'Orthopédie, 1or March, 1896, p. 228.

¹⁶ Zeitschrift f. orthopädische Chirurgie, 1896, Band iv, Heft 2, p. 473.

flat-foot, which results from a peculiar position of the foot, that in order to avoid pressure upon the painful part of the inner edge of the foot. The foot presented a pronounced flat-foot, the astragalus and scaphoid being very prominent. The head of the metatarsus is very prominent, and the first phalanx of the great toe is flexed almost at right angles with the metatarsus. The second phalanx rests upon the ground, and the remaining toes are more or less flexed. The flat-foot is not fixed but movable. The writer was not inclined to consider this due to any painful pressure on the foot, but a form of late rickets and considers it a form of flat-foot primarily, and that the deformity of the toe is the result of the pressure of a wooden shoe upon the end of the toe; exostosis followed which flexed the toe more and more.

CONGENITAL DISLOCATION OF THE HIP REPLACED BY OPERATION.

Mr. Openshaw²⁰ showed a girl, aged three, who came to him presenting the typical appearance of congenital dislocation of the hip. He cut down into the joint, removed a portion of the iliac bone at the upper and back part of the acetabulum, and gradually wiggled the head, which was normal in shape, back into the cavity. The shortening, which was previously one and one half inches, was reduced to three-fourths of an inch, and she could walk with a slight limp. The movements of the joint were free in almost every direction, it being four months after the operation. He pointed out that unilateral cases were more favorable for operation than bilateral — the head could not very well be replaced in the cavity before two and one-half years, on account of the contraction of the acetabulum. The head of the bone generally became flattened after the age of eight, if it remained dislocated.

CONGENITAL DISLOCATION OF THE HIP.

Dr. James Taylor²¹ showed a woman, aged twenty-three, who came under his care for epilepsy. He noticed that she was lame, and on examining her he found that there was probably congenital dislocation of the hip. Dr. Ballance concurred in this view. It was peculiar in that there was very great mobility of the joint, this being associated with abnormal mobility in the corresponding knee as well as in the opposite knee. The limb was much shortened, with corresponding lateral spinal curvature. There was much grating on moving the femur, and it sometimes seemed to slip into a hole as if there were the remains of an acetabulum. Mr. Wallace said that after seeing this patient walk and noticing how easily she did so, he was disposed to congratulate her on having escaped operative interference. Mr. Gordon Brodie recalled the case of a lad with a similar condition who could walk several miles without inconvenience; and under these circumstances he, too, was inclined to consider nature's method of cure the best. Mr. Brattle observed that in this case there seemed to be very little neck left; and he presumed that, as in cases of injury, there had been some atrophy and absorption of the upper end of the bone. He suggested that the condition might possibly be the remains of an attack of infantile paralysis. Dr. Taylor said that idea had occurred to him, but he had not been able to elicit any

information pointing to any such attack. The whole limb was smaller, probably from want of exercise.

Brodhurst²² gives his opinion from his experience in 52 cases in 35 years. He regards this affection as having for the most part a traumatic origin, and holds that it may be best treated by subcutaneous myotomy and subsequent extension of the limb, and in cases in which the acetabulum is filled up, by subcutaneous gouging of this cavity. If retraction of trochanteric muscles has not taken place, the head of the femur, he states, may be immediately replaced in the acetabulum and there be retained.

Schanz²³ contributes an excellent review on the subject of operative interference for the correction of congenital dislocation, giving a history of the methods recommended and the modifications by Lorenz, awarding the chief credit of the operation to Hoffa. A table of the cases that have been operated upon is given and the results. The writer is inclined to take issue with Lorenz, who claims that an incision dividing the muscles is a great injury to them, and fails to find any case where a muscle loosened from the trochanter not only did not heal, but did not recover its function. Almost all operators have used the incision of Langenbeck. A few favor an incision upon the side in order to give more freedom in the anterior division of the capsule and especially the Y ligaments. It is essential not only that the anterior capsule should be divided, but also that the acetabulum should be sufficiently deepened, and that there be no tendency for a subluxation to take place. The writer is not in favor of placing a needle in the upper portion of the acetabulum to prevent subluxation, as had been suggested. Forcible motion after an operation is not necessary, and in most of the cases in Hoffa's clinic, good motion is obtained ultimately. In the ultimate results of the operation in the list collected by the writer, seven cases died from sepsis, and in all these the wound was closed by suture. In four cases death followed from intercurrent disease. In eight cases the result was poor, that is to say, relapses occurred. In six the cases were neither good nor bad; in two the joint being ankylosed and in one an ankylosis was expected, but in 109 cases the result is reported as entirely satisfactory.

Paradies²⁴ reports several cases of the operative treatment for pseudo-arthritis in double congenital hip in older patients at Hoffa's clinic in Würzburg. He claims that patients above ten years of age (too old for radical cure) with double congenital dislocation are suitable for this operation, which aims at a firmer union with the ilium at the upper end of the femur then the distortion alone gives, the fact being that under ordinary circumstances the dislocated head of the femur can form no proper joint upon the ilium, because it does not lie in direct contact with it, but is separated from the ilium partly by the interposing capsule and partly by the ligamentum teres. If this is extirpated and the interposing capsule is removed, the head and neck can come in direct contact with the ilium. The deformed head is sawn off, and the freshened end of the femur is placed in contact with the freshened portion of the ilium. Twelve cases are reported with good results.

Lorenz²⁵ in a monograph on the subject, based his

²¹ Loc. cit., p. 595.

conclusion upon a hundred cases of operative reposition by means of incision; he finds that the gluteus maximus, a portion of the pelvi femoral and the pelvi crural muscles, especially the latter, are the most important obstacles to reduction. He thinks that the ileo psoas muscle and the gluteus, which passes over the head of the femur and the trochanter, do not offer any resistance to reposition. The affection may be mistaken for the coxa-vara, coxitis and luxation after an osteomyelitis. He considers that there is no conflict between the mechanical and operative treatment, where the first is possible it is sufficient, but after five years of age, operative incision is usually necessary. He has modified the method of forcible reduction recommended by Paci. He recommends traction for several days in order to lengthen the limb, and makes an incision along the outer border of the tensor vaginæ femoris. He opens the capsule by a T-incision.

Hoffa²⁶ reports the ultimate results in his operations upon congenital dislocation — nine being for the formation of an artificial pseudo-arthritis, already mentioned; one being a double resection; 82 of operative reposition through incision. Thirty of these were double and 52 single. There were seven deaths, three being in connection with pneumonia, diphtheria and intestinal catarrh; four being from shock. These deaths Hoffa considers can be avoided by an improvement of the technique. He recommends strict asepsis, and the use of a sterilized gauze tampon, and in his last 47 cases he has met with no misfortune. There was ankylosis in nine cases, and in eight of these there were suppuration from a wound that was sewed. Hoffa has never found a dislocation backwards, but he has in eight cases met with a transposition forward, following the operation. This can be avoided by deepening the acetabulum.

RESECTION OF THE RIBS IN SCOLIOSIS.

Hoffa, of Würzburg,²⁷ reports a case of severe scoliosis in a boy on whom he performed an unusual operation by a resection of a portion of the ribs. This operation was first suggested by Volkmann in 1889. Orthopedic treatment had been unsuccessful, and the case was a pitiable one. The patient is said to have been much improved by the operation. The operation was repeated by him in a second case; but with these exceptions no surgical interference has ever been undertaken in scoliosis until that reported by Hoffa. The patient was a boy ten years of age, and presented a severe rickety curvature of the spine, which had increased in spite of treatment. The patient was pale and weak, and with a marked projection of the ribs sharply bent; gymnastics and apparatus had been thoroughly tried by Hoffa, with some development of the muscle, but with no improvement in the deformity. The patient was laid upon the face, the left arm raised to remove the scapulæ; an incision of the skin was made from the upper border of the deformity of the ribs, downwards to the lower border of the same. Various muscles were divided, and a subperiosteal resection was made at the ninth rib at the point of its greatest projection. The seventh and eighth ribs were also divided in the same way in the line of the axilla. The sixth, fifth, fourth and third ribs were twisted out of their vertebral articulations. The pluriæ were slightly perforated during the operation.

but caused no trouble. After the operation the thorax was fixed by adhesive plaster, and the patient was able to go about eight days later. The procedure not only improved the appearance of the patient, but it enabled the surgeon later to effect considerable correction in the deformity through gymnastics. This is clear from the result of photographs shown in the paper. The patient not only was given to gymnastic treatment, but a specially devised corset was used and worn. Hoffa recommends in severe scoliosis, not only to resect a portion of the rib, but on the concave side to make a lineal osteotomy of the concave ribs. This would enable him to arrange for a correction of the twist of the spine.

THE USE OF THE BICYCLE IN THE TREATMENT OF SCOLIOSIS.

Dr. Kiliani²⁸ reports a device by which he uses the principle of the bicycle in the treatment of scoliosis. He distinctly states that he considers it simply one link in a long chain of therapeutic means, but regards it as a valuable method of muscular development in positions which are in themselves corrective. His device is so arranged that the height of the saddle can be changed, its obliquity, the height relative to the position of the pedals and the relative position of the two sides of the saddle. By the changes, combined with the difference in height or the length of the pedals on the two sides, an obliquity of the pelvis is obtained, and the person is allowed to use the muscles in this position, which is corrective of some of the conditions found in scoliosis. By his device he is enabled to change the relative position of the two sides of the handle-bars, by which the position of the upper part of the spine is influenced, so that the deformity can be untwisted, as it were, while at the same time the muscles of the lower part of the trunk are made to work in such positions as favors their correction. The machine is so arranged that it may be used as a home exercise, but it is also possible to apply the method to the bicycle as used for exercise.

LATERAL CURVATURE.

Delore²⁹ recommends forcible correction in scoliosis. The patient is etherized and placed on the side, with a cushion under the axilla and pelvis, and considerable force used upon the projecting ribs; adhesions are broken down, and the ribs and spinal column moved into correct positions by force. Sometimes the correction is easily made, at other times a great deal of force is necessary; but no evil results have been met by Delore. The patient is placed in a fixed bandage, and later correction twice a day is undertaken and a specially constructed corset used. At night a specially devised couch is used, the patient lying upon the right or left side. Suspension can be added to this method of treatment.

LUXATION OF THE SESAMOID BONE OF THE GREAT TOE. — The diagnosis of a case of this injury by means of a skiagram is reported in the *Lancet* by Thorburn. The injury was the result of a weight falling upon the foot, and the ensuing pain incapacitated the patient for work. Reduction was impracticable, but a cure resulted apparently from cutting down on the bone.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

J. G. MUMFORD, M.D., SECRETARY.

MEETING of November 30, 1896, DR. F. H. WILLIAMS in the chair.

DR. E. H. BRADFORD called attention to the

VALUE OF MECHANICAL EXERCISE IN THE TREATMENT OF STIFFNESS OF THE JOINTS.

After traumatism or inflammatory changes, an impairment of elasticity of the ligaments follows, which impedes motion and, unless corrected, cripples. A stage is reached when motion as a therapeutic measure is indicated. This must be painless, to prevent reflex muscular spasm, which protects the impaired ligaments, and should be frequently repeated.

Forcible correction may be needed to break adhesions, but it is ineffectual as a constant daily exercise; that improvement may be followed by careful efforts is illustrated by two cases.

Dr. Bradford spoke of the method of mechanical exercise recommended by Zander and in use in the various Zander establishments, and also the appliances devised by Krukenberg, of Halle, and showed a modification of Krukenberg's pendulum apparatus to be used for stiffness of the knee, hip, elbow and shoulder joints.

This method may be found also to be applicable in other groups of muscles.

DR. HARTWELL: I suppose Dr. Bradford has asked me to open the discussion on this subject because of the reference he has made to the mechanical gymnastic treatment devised largely by Dr. Zander, and because it happened some years ago that I had the opportunity of spending some time with Dr. Zander. It is interesting to see how Gutenberg has evidently profited by some of the Zander devices. The figures suggest that he has studied pretty carefully the Zander machines and then patented his ideas in a way to imitate them. The Zander machines have not been patented, so far as I know. It is also very interesting to see how this mechanical line of treatment is becoming more and more developed in order to supplement the mechano-therapy of manipulation by the masseur and the medical gymnast. It was very largely with that in view, I presume, that Dr. Zander, in the home of Swedish-movement treatment, developed his system of machines and treatment. The series of Zander machines numbers something like fifty, divided into two great groups: those run by power and those to which are applied the active movements and motive power found in the muscles of the patient himself. They were exhibited in this country in 1876 at the Philadelphia Exposition. They have afforded confirmatory suggestions to some inventors of gymnastic apparatus which have proved popular and widespread in this country (for circumscribed muscular exercises). My attention was called to them twelve years ago because of their great ingenuity; and they were then, in 1885, in the Institute in London as well as in use at the bath establishment of Baden-Baden. Since then the Zander institutes have multiplied in large numbers; and in these pamphlets, which I will pass around, are some maps showing by dots in red the location of the leading Zander institutes. The machines have

been put in by the new Kaiserbad at Carlsbad, an institute in Dresden, Frankfort, Vienna, etc. They are divided into these two general classes: those run by power afford the passive movements; and also another set of manipulations which are difficult to give and give satisfactorily in force with the hand by an accomplished masseur or gymnast, namely, the vibrations and the various forms of shock and blow which by properly graduated hammers and cushions may be applied to any part of the body, including joints. That class of machines as well as this, which corresponds to this class which Gutenberg has developed, also constitute a part of the series of the Zander armamentarium for the treatment of joint diseases.

The year I was with him about 30 per cent. of Zander's cases were cases in which there was some disease or trouble of the organs of movement or locomotion, and the next largest class of cases were cases of heart affection, about 20 per cent. Dr. Bradford spoke of the good effect of riding. Zander has a machine for horse exercise which can be moved so that you can use a side-saddle or ordinary saddle and get a good deal of vibration and shaking out of it. I think what would be of most interest to us to consider is the fact that there has been developed in Germany, chiefly through the initiative of the director of the Zander institute in Berlin, an institute which was formed, as such institutes ought to be, through the action of an association of physicians responsible for it and to whom the director was responsible. Dr. Schultz, of Berlin, has been instrumental in developing an asylum for the treatment of injured persons, that is to say, distinctly for the treatment of persons who have injured their joints or bones and who need after-treatment following their discharge from the hospital; and he has developed it in connection with certain associations of workmen. At first, in 1891, the patronage was chiefly in the asylum, situated a few miles north of Berlin, where a house was fitted up with a full set of the Zander machines, in connection with improved baths, electricity and appropriate manual gymnastics and massage. (It should be said that in the Zander institute massage is not given by machinery.) It is distinctly understood that he has not attempted to devise massage machines. There is a great deal of massage given by skilled masseurs, most of whom have been trained in Germany. The especial trade-union which patronized this asylum near Berlin in 1891 was the Carter's Union, and most of the men brought into that were men who had fallen off wagons, had injured their joints, and had suffered from the ill effects of weakness, atrophy, etc. Now there was a pecuniary end in establishing this institute—to see if they could not relieve the union of paying stipends for too long a time, and a certain number of cases came in for observation by skilled physicians to see whether the degree of injury which the patient claimed prevented him from work, was genuine or not; and only a certain portion of malingerers was found—about four per cent., I think, in the two years of which I have the reports; and the result was that the management of that trade-union was so satisfied that a number of other unions undertook to obtain the benefits of the asylum so that there were 300 more patients the second year than the first.

I will give a few figures to show what class of cases they had and what in general the results were. In the second year 625 cases of injury were received into

the institute and 533 discharged. The other 92 were still on hand for further treatment, and there are no less than 49 different associations of one kind and another represented in the patronage of this institute, including some dozen railroad associations in Germany who sent their injured cases for treatment there. Now, of the 533 cases treated in this year and discharged, 50 per cent. had had fracture of the bones, 5 per cent. had luxations, 1 per cent. strains, 17 per cent. contusions, 19 per cent. wounds in the soft parts, and 5.5 per cent. other injuries. The most numerous cases of fracture had been of the leg, next of the thigh, then of the forearm, then of the upper arm, besides all sorts of breaks in other parts of the body. It is interesting to note that in this second year the average time which had elapsed after the injury before the patients were received at this place was twelve months. There were 229 patients that came in within the first half-year after the injury, 154 in the second half, 139 after the second half-year, etc.; but the improvement in the general statistics of the association over the previous year was in proportion as the patients came up for treatment earlier, and the average time of treatment or stay in the institute was seven weeks during the second year, whereas it had been nine weeks in the first year. The age of the patients varied from fourteen to seventy-three years: 29 between sixty-one and seventy, 104 between fifty-one and sixty, the greatest number 146 between thirty-one and forty. Of a certain proportion, 163 of the 533 discharged, 28 were turned out with fully restored power—6 per cent. of that number; 33 per cent. were turned out with still some slight loss of power and the amount of inability was adjudged not only by the physician but by a court of reference in which the leading insurance companies were represented. About one-fourth of those that had been under treatment in this class came out very nearly fully restored; considerably improved, from 50 per cent. to 100 per cent; improvement in the matter of ability to go on with their craft, in 43 per cent. of the whole; etc. The practical point as regards the value of this institute to the associations engaged in the insurance of workmen comes from the financial balance. The whole cost of the treatment (three marks a day) is charged to the patients, counting stipends to the wives and children of the disabled men; that all comes to about 24,000 marks; and in diminished stipends from the treatment and improvement to the men the figure is over 30,000 marks; so that apparently Dr. Schultz makes out a saving of 6,200 marks for the cases directly under treatment.

DR. H. P. BOWDITCH: I have prepared no formal contribution to this discussion, but I have been very much interested in all that has been said about passive movements for the treatment of diseases of the nerve-muscle mechanism of the body, and it seems to me that since they have been found so successful and useful in many cases, it is interesting to consider some of the physiological principles on which such treatment must rest. Of the simple mechanical uses of such treatment, such as breaking up of old adhesions or stretching of contracted and diseased ligaments, I need not speak. There are a number of processes connected with the movements of the joints which must necessarily be affected by passive as well as by active movements, for it has been found that among the different phenomena which are connected with

movement, some of them seem to occur in connection with muscular contraction, that is, certain processes go on in the muscle because it contracts, while others take place not because the muscle contracts, but because the joints move. The fact of movement is, therefore, an important circumstance in connection with the nutrition of the parts, and not simply the fact that the muscles contract. Of course, all the phenomena which occur in consequence of the movement and not on account of muscular contraction are largely to be imitated by passive movement. Among these phenomena are to be classed in the first place, the movements of the lymph. The lymph moves in obedience to the laws of hydraulics in consequence of the fact that the fasciæ about the muscles are stretched and relaxed whenever the muscles move. The contraction of the muscle and the movement of the joints continually relax and stretch the neighboring fasciæ, the lymph spaces between the tendinous bundles are opened and closed, and the lymph is sucked away from the side nearest the muscle and carried on through the lymph spaces into the lymphatic vessels and into the great lymph trunks. This important influence of the fasciæ in keeping the lymph moving has been demonstrated by physiological experiments. In the second place the respiration of the tissues is to be considered: going on in all parts of the body, and largely increased by the activity of the organs, are certain chemical changes which find their final expression in what has been called "the respiration of the tissues," that is to say, the blood loses oxygen and gains carbon dioxide. It has been found that this gas exchange of the tissues, which is complementary to that which takes place in the lungs, is affected both by the movements of the limbs and by the fact that the muscles contract. It has been found that the muscular contraction is the main element in determining the amount of carbon-dioxide liberation whereas the fact that the joint moves, seems to determine very largely the oxygen absorption. The muscle liberates carbon dioxide in consequence of its contraction. That is not necessarily at the same instant associated with absorption of oxygen. Oxygen has to be absorbed to keep pace with it; but the fact of muscular contraction seems to be the determining influence in setting free carbon dioxide, whereas movements of the joints influences the amount of oxygen absorbed. By passive movements, therefore, the amount of oxygen available for muscular catabolism can be increased without necessarily setting free the corresponding amount of carbon dioxide; so that there is no doubt that passive movements are very useful on this account as well as for other reasons. It seems to me, too, that the question of passive movement is a very important one in other ways. When a movement takes place actively, no matter how gentle the movement may be, the articular surfaces are pressed together. Even in a very slight movement, a considerable pressure must be exerted on the articular surfaces. In arthritis, it seems to me, this is what should be avoided. This may be the reason why passive movements are often so much more useful than active ones in a great many cases of joint trouble. This is more particularly the case in joints of the lower limbs which bear the weight of the body, for it is impossible to exercise those joints naturally without subjecting them to a good deal of pressure by the weight of the body. The usefulness of such apparatus as Zander machines where the limb is placed

in a piece of machinery which moves it, is perhaps largely to be explained in this way. It seems to me the time has come when we ought to have in this city the advantage of such therapeutic facilities as are afforded by a Zander institute. While there are some thirty odd Zander institutes in Europe, we have only two sets of apparatus in America. I believe there is a portion of a set in New York and one in St. Louis. It seems very desirable that we should have something done here and I cannot help thinking that, if it has been so successful in Germany, the institute must be largely self-supporting. It seems to me that among the various classes of cases that seem to be benefited in this way the number of patients will be found sufficient to justify the establishment of such an institute in this city.

DR. GRAHAM: There is one use to which this apparatus can be put which Dr. Bradford did not point out. While it is excellent for passive motion it can also be used for resisted motion where the joint is not too stiff. It is a good plan to let the patient exercise himself occasionally, and, moreover, Dr. Bowditch would tell us that muscles that are contracted in lifting a weight will extend more than muscles that are relaxed and being pulled out by the same weight; so that if we take stiff muscles, it will be of advantage to stretch them in both directions and get so much more passive motion. We have all been considering the effects of stiff joints, what Oliver Wendell Holmes used to speak of as investigating fireworks after the Fourth of July. It might be worth while to say something about preventing these stiff joints. Going through the large hospitals we see fractures beautifully put up, and we see two or three joints being made stiff for one fracture to unite; and when the poor patient gets out of the hospital it takes him, two, three or six months to get over the stiffness that might have been prevented by a little massage and passive motion while the fracture was uniting.

DR. J. E. GOLDTHWAIT made a preliminary report on

THE DIRECT TRANSPLANTATION OF MUSCLES IN THE CORRECTION OF DEFORMITIES.

In a paper read about a year ago on the subject of tendon grafting or transplantation I made the suggestion—and in that paper the work was confined entirely to the grafting of tendons about the feet—that in all probability the same principle could be applied to other parts of the body, and that probably the muscles of the thigh could be used to help out those which had been paralyzed, and in other parts of the body the same principle could be worked out. In developing that work a clinical study was made of the cases of infantile paralysis so commonly seen in the orthopedic and nervous clinics, in which the muscles of the thigh were more or less involved; and in a very large number of cases all of the anterior thigh muscles were found to be paralyzed, with the exception of the sartorius and the tensor vaginae femoris. On looking up the nerve-supply, it seemed rather an unusual condition, because the anterior crural supplies the sartorius as well as the other muscles; but Dr. Dwight kindly looked up the minute anatomy, and reported that the fibres going to the sartorius came from the second and third lumbar nerves and the fibres going to the others came from the branches of the lumbar plexus below that. The attempt was made to use the sartorius as

an extensor, and this young woman has come to-night so that I could show the result of that operation. She has infantile paralysis of the right leg, practically all the muscles of the lower leg being involved, and the muscles of the thigh were all involved, with the exception of the sartorius, and the gait was the characteristic flinging gait. About six months ago an operation was done and the sartorius muscle transferred. Before this there was no power of extension and the sartorius served simply to jerk the leg sidewise. Now she can lift and completely extend the leg. She has lost that flinging gait entirely. The limp is largely due to the fact that the tendo-Achillis and the posterior muscles were all contracted and she walked on the toe. She wears a brace holding the foot so that it cannot drop down, and the gait is partly due to that. Before the operation, having no anterior thigh muscles, it was impossible to bear the weight on the leg. The knee gave way, and down she would go. Now she can walk. In doing the operations one thing very noticeable was the fact that with the extreme atrophy of the anterior thigh muscles you have a condition something like this (diagram shown): the sartorius starts properly at the anterior superior spine, and passes directly under the skin across this thick mass of muscle down the inner side of the tibia. This mass of muscle acts as a fulcrum over which the sartorius pulls so that the muscle in a state of health is an outward rotator of the thigh, and an extensor as well. Now this fulcrum being so high, lifts the leg as well as rotates it. When the fulcrum is lost so that the quadriceps is represented by a thin membrane, the sartorius comes down directly against the bone, and it gradually slips round to the side, so that instead of finding the sartorius on the inner side well toward the front, the muscle is found way round to the back behind the adductor muscles. In the first operation I attempted I did not find the muscle. The next time it was found at the back, and it has been found in the other cases in the same place. One plan was to attach the muscle in the middle of the thigh; but this is not satisfactory, as you lose half of the contractile power of the muscle. The results are not as good as where the attachment is made directly above the patella. If it is possible the attachment of the sartorius muscle is not severed at all; if the muscle is long enough so that it can be drawn up and sewed to the tendon, the attachment is made and no harm can result; but if the muscle is so much contracted, as it has been in several cases, so that it is impossible to loop the muscle up, the sartorius tendon is divided and the end of the muscle sewed through and attached just above the patella. In this case you see the muscle was left at this point and not divided.

The only other satisfactory case of muscle transplantation I wish to report is one undertaken to correct one of the defects which has been encountered in doing the tendon-grafting, and that is in the tendons of the anterior part of the foot. The common tendon to which the attachment is to be made is the peroneus tertius, because that muscle commonly escapes paralysis, and the tendon of that muscle is so small that sloughing has taken place where the greatest care has been used; and to correct that, the operation has been done of cutting down on to the muscles just before the tendons are given off, the muscles separated and the muscles sewed directly through before the tendons are given off, so that the pull comes

through the end of the muscle rather than through the tendon. It is an easier operation; there is no danger of sloughing; and in a condition where the tendons are very small, it is the better operation to do.

DR. HARRINGTON: I have very little to say. Dr. Goldthwait was kind enough to help me in a case of tendon and muscle transplantation at the Massachusetts Hospital. I wish to express my admiration for the work which Dr. Goldthwait has done in this direction. The sartorius muscle on both thighs was attached to the tendinous tissues just above the patella. I have not yet allowed the patient to use these muscles. In this same case the transplantation of the tendons of the foot was very successful.

In both thighs the sartorius was displaced backward, as Dr. Goldthwait has said, and was found with difficulty in the first search. The search for the second muscle was much less difficult.

DR. BRADFORD: Dr. Goldthwait was kind enough to allow me to examine one of his cases six months after he had operated upon the patient, and I can gladly testify to the excellent results. The procedure of muscle-grafting of the sartorius is a new one, and the credit of it belongs to Dr. Goldthwait, who has enlarged his experience in tendon transplantation, adding to it cases of muscle transplantation, utilizing the sartorius to supplement the work of the extensor-cruris muscle. Judging from the results which have been gained the new method promises to be of great value. If it is tried in younger children, it can be expected that the muscles will adapt themselves to the new condition, and there is no reason why we cannot expect that the sartorius may become enlarged by use and growth, replacing the paralyzed quadriceps.

Recent Literature.

A Handbook of Pathological Anatomy and Histology. By FRANCIS DELAFIELD, M.D., LL.D., and T. MITCHELL PRUDDEN, M.D. Fifth edition. New York: Wm. Wood & Co. 1896.

This, the fifth edition of this well-known work, appears as an attractive volume of 800 odd pages. The introduction of many new wood-cuts and the revision or rewriting of all of the sections of the book make it a very satisfactory presentation of the important facts and prevalent ideas on the subjects of Pathological Anatomy, Bacteriology and Pathological Histology. The subject-matter is divided into four parts:

Part I contains directions for making autopsies and some of the more important methods of microscopical examination of pathological tissues.

Part II is devoted to the consideration of general pathology, including the infectious diseases, parasites, tumors, and the pathology of the circulation. It also includes a chapter on the changes in the composition and structure of the blood, by Dr. James Ewing, in which is given a brief account of the microscopical characteristics of the blood in the various forms of blood disease, as well as a short description of the technique of blood examination.

Part III is entitled the "Morbidity of the Organs," and contains brief descriptions of the gross and microscopical appearances of the various important lesions met with, including a good chapter on the nervous system.

Part IV deals with the lesions found in the general diseases, in poisoning and in violent deaths. The discussion of these subjects is brief and to the point.

The book thus covers a wide field. It commends itself for its concise statement of facts; for its brevity and clearness of description. Its chief merit, however, is the great number and excellence of the wood-engravings, nearly all of which are original, illustrating the microscopical anatomy of tumors, and of pathological tissues generally.

The work can be sincerely recommended to students and practitioners of medicine who do not desire an exhaustive consideration of the subjects treated.

Twentieth Century Practice. An International Encyclopedia of Modern Medical Science. By leading authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D., New York City. In twenty volumes. Vol. VII, Diseases of the Respiratory Organs and Blood, and Functional Sexual Disorders. New York: William Wood & Co. 1896.

The contributors to this volume are Drs. Charles W. Allan, New York; Jules Comby, Paris; Charles G. Cumston and Ernest W. Cushing, Boston; James M. French, Cincinnati; E. Fletcher Ingals, Chicago; E. Main, Paris; Franz Riegel, Giessen; Alfred Stengel, Philadelphia; Herbert B. Whitney, Denver. Most of these gentlemen are connected with some medical school or hospital, or both.

The subjects treated of in this volume have no especial connection with each other.

The most important articles are those by Dr. Whitney, on "Diseases of the Respiratory Organs," and by Dr. Stengel on "Diseases of the Blood."

Dr. Allen's contribution is on "Functional Disorders of the Male Sexual Organs," Drs. Cushing's and Cumston's on "Disorders of Menstruation." Dr. Ingals's paper on "Hay Fever" tells what is known on that subject and gives the result of his personal experience, with treatment. Riegel, who writes on "Asthma," is the author of the paper on "Bronchial Asthma," in "Von Ziemssen's Cyclopædia, 1876."

This volume contains, with the index, 796 pages. Volume VIII has already been published.

A Text-book upon the Pathogenic Bacteria. For Students of Medicine and Physicians. By JOSEPH MCFARLAND, M.D. With 113 illustrations. Philadelphia: W. B. Saunders. 1896.

The publisher has made a very attractive book out of this volume of about 350 pages. It is plentifully supplied with excellent reproductions of microphotographs of bacteria, most of which have been taken from the well-known "Atlas" of Fraenkel and Pfeiffer. Various subjects are also well illustrated with wood-cuts selected from various other books dealing with bacteriological subjects. Original or new illustrations are very few. A reproduction of Löffler's colored plate of the potato culture of the bacillus of glanders adorns the page opposite the title-page. It was probably placed in this prominent position on account of its rather striking colors.

The paper and printing are excellent. The author's part in the preparation of the book is not very remarkable. The usual facts have been presented in the usual way. The volume can be recommended to those who wish to secure by reading some knowledge of the pathogenic bacteria and the methods of bacteriological research.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, FEBRUARY 18, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

RECENT ADVANCES IN NEUROPATHOLOGY.

AMONG the most hopeful and significant phases of recent progress in medicine is the constantly increasing attention given to pathology and pathological anatomy. It is coming to be generally recognized that observation and experience are frequently false guides, and that empirical methods of studying disease need always to be supplemented by an appeal to underlying morbid conditions. Processes are demanding attention, and symptoms are being relegated to their normal scientific position, as the physiological expression of such processes. We are already reaping the fruits of our broadened attitude in a clearer comprehension of the various groups of symptoms, which we more or less accurately designate as diseases, and the future is full of hope that a classification may ultimately be made which will satisfy the scientific intelligence, as well as the mind of a purely practical bias. This, certainly, it is the function of pathology in its broadest sense to accomplish, and the results thus far attained allow of no reasonable doubt that the task is not an insurmountable one.

Owing to the infinitely complex and subtle functions of the nervous system, it is in no way to be wondered at that knowledge of an exact sort has lagged behind that of other organs or systems of organs. Nevertheless, the revelations of the last few years, even in this field, have been so suggestive, that we may look forward with confidence toward generalizations of wide-reaching significance. This progress has been due to but one thing—the recognition of the necessity of a rigid scientific method of investigation. With the growth of this feeling, and as a necessary consequence of it, pathological laboratories have come into existence at many institutions for the insane, where but a few years ago they were supposed to have no field of usefulness whatever. New York State has gone still further, and established in New York City, under the able directorship of Dr. Ira Van Gieson, a

central pathological institute, whose function shall be to direct the work of the several laboratories throughout the State, and at the same time serve in itself as a centre of research. There can be no doubt that the establishment of such a laboratory or system of laboratories is one of the most significant steps of recent years toward the foundation of a scientific spirit regarding neurological problems. Van Gieson's brilliant address, on "The Toxic Basis of Neural Diseases,"¹ forces us to an entire agreement with him in his hopes for future work. Reverting to certain statements made in a previous address relating to the fact that he believes that "certain factors are at hand for the creation of a new epoch in the evolution of the pathogenesis of nervous and mental diseases," he goes on to say:

"The first and most important of these factors is the precise and definite status which the anatomy of the nervous system attained through the investigations of the past decade by the Golgi methods; the establishment of the neuron theory in particular leads to a definite understanding of the pathology and physiology of the nervous system."

"A second great factor in this new epoch of neuropathology is the application of the modern doctrine of cytology and its technical methods of research to the investigation of the problems in nervous and mental diseases."

"A third factor is a realization of the absolute necessity of correlating the nervous system with other organs and tissues in the body in studying the operation of the fundamental and general somatic pathological processes in the nervous system."

In these three statements lies the substance of our present point of view regarding the pathology of the nervous system. Certain points are of particular interest, and by no means sufficiently realized by the medical profession at large. The significance of the Golgi methods in the light they have thrown on the fundamental principle of anatomical structure received a quick recognition. The neuron theory needed only to be advanced to be accepted, so reasonable did its fundamental idea seem to be. As applied to pathology, however, it had been accorded a much more tardy recognition, on account, no doubt, of the deeply-rooted conception that cells and fibres did not essentially belong together. Because of our failure to recognize in the neuron a unit of histological structure, we have been unable to apply a true cellular pathology to our investigations of disease processes in the nervous system. When, however, it becomes a habit of thought to conceive of the highly differentiated nerve cell as we do of the simpler liver or kidney cell, it will be at once evident that we may apply to the nervous system those general pathological principles which are everywhere else operative—a step certainly of much significance.

The second point upon which Van Gieson dwells is of almost equal importance, namely, the elaboration

¹ State Hospitals Bulletin, 1896, Vol. i, No. 4.

of new technical methods of research. It is entirely natural that the highly differentiated nerve cell should demand for its proper investigation staining methods of extreme refinement and delicacy. Until methods were found which could demonstrate minute structural alterations it was hopeless to expect any material advance in our knowledge of the subtle anatomical changes underlying and associated with many marked clinical phenomena. This difficulty is now, in a measure at least, a thing of the past. We have come clearly to recognize that transient injuries to the nerve mechanisms leave their impress, as well as those of greater severity and longer continuance. We are now no longer deterred from histological investigation, which a few years ago, would, of necessity, have been fruitless owing to inadequate methods.

A matter of extreme general importance is Van Gieson's third factor, in which he speaks of the necessity of correlating the nervous system with other organs and tissues in studying its pathological processes. We cannot do better than quote his own words relative to this point:

"However obvious or trite," he says, "the statement of this third factor may appear, it is nevertheless true that much of the present obscurity in the pathogenesis of nervous, and especially of mental diseases, is largely to be explained by the very simple fact that the brain and the rest of the nervous system have been studied altogether too much as something apart from the rest of the body—as something beyond the jurisdiction of the laws of the great fundamental pathological processes which operate on the whole organism."

Van Gieson insists that the nervous system cannot be exempt from the workings of pathological laws which are elsewhere operative, and that we must recognize this fact if we are to progress. Of necessity, the manifestation of such laws in the nervous system, as elsewhere, must depend upon the peculiar differentiation of the ultimate histological elements, but because the nerve cell is highly differentiated affords no reason that it must be governed by pathological laws peculiar to itself.

We owe Van Gieson a debt of gratitude for having clearly stated this broad point of view, and for his insistence upon the fact that the nervous system is, after all, merely a part of the organism as a whole, and therefore must be amenable to the same laws of disease and decay.

Space is not permitted us to discuss in detail the skilful application of the principles above stated to a consideration of the present theories and facts regarding the toxic causes of many nervous and mental affections. He sees in such agencies, taken in the broadest sense, an etiological factor of the greatest importance. His view is a somewhat radical one, but nowhere does it lose its absolutely judicial spirit. Unquestionably, the line of investigation presented in the paper from which we have quoted, is one which, if carried out on the strictly scientific lines laid down, will

yield results of the utmost importance. Van Gieson insists upon the value of minute examination of cells, as giving indication of a toxic process, when such toxic agent may be in itself unknown. For example, he says:

"While little or nothing may be known about the nature and source of subtle and seemingly intangible pathogenic poisons, beyond suspicions of their existence from the clinical history, nevertheless, existence in the body of these poisons may be postulated and their causal relation to the neural clinical manifestations may be determined by the morphological changes of parenchymatous degeneration recorded in the nerve cell by their toxic action."

The address is full of suggestiveness from beginning to end, and marks, no doubt, the beginning of more painstaking and systematic work than has yet been done on the general subject of the pathology of nervous and mental disease.

MEDICAL NOTES.

DU BOIS-REYMOND'S SUCCESSOR.—Professor Munk, of Berlin, and Professor Kühme, of Heidelberg, are being considered as successors to the chair of physiology at Berlin University.

A RINDERPEST SERUM.—Professor Koch is reported to have succeeded in preparing a serum which will lessen the virulence of rinderpest. Whether it has any protective power is not stated. He is soon to return to Berlin.

THE NEW YORK POLYCLINIC HOSPITAL.—The trustees of the New York Polyclinic Medical School and Hospital have decided to rebuild on the site of their former building, which was burned some weeks ago. The work will be begun immediately.

BRONZE MEDAL CURE OF CANCER.—The daughter of the principal notary of Piacenza, Italy, was found to have in her stomach an accumulation of medals of a Madonna locally celebrated for powers of cure in cancer. She had swallowed a medal each day for a week on advice of her confessor. — *The Churchman*.

COLLARETTES AND DERMATITIS.—Two cases of dermatitis of the neck caused by the wearing of sable collarettes were reported in the *Lancet* of December 12, 1896. Chemical examination in one case showed that there was no arsenic or other irritant drug in the fur, and the trouble is believed to have resulted from mechanical irritation.

ANGEL MAKING IN RUSSIA.—A telegram from Odessa to the *London Daily Mail* reports the trial of a woman and her three daughters at Ekaterinburg, during the course of which it was proved that the charge for "angel making," the euphemism applied to infanticide, was five shillings an infant. Death was brought about mainly by withholding food, and by general neglect.

MEXICO HONORS PASTEUR.—The municipality of Mexico has given the name of Pasteur to the gardens situated in front of the National School of Medicine in that city.

THE TETANUS ANTITOXIN.—Four cases of traumatic tetanus which entered the Cook County Hospital, Chicago, between September 20th and October 10th, were treated by tetanus antitoxin, and three of the four recovered, according to a report in the *Journal of the American Medical Association*.

DR. ABBOTT SUCCEEDS DR. BOLTON.—Dr. Alexander C. Abbott, Professor of Hygiene in the University of Pennsylvania, has been appointed chief of the bacteriological division of the Philadelphia Bureau of Health, in succession to Dr. B. Meade Bolton, resigned.

THE FIFTEENTH GERMAN CONGRESS OF INTERNAL MEDICINE will be held in Berlin on the 9th, 10th, 11th and 12th of June, under the presidency of Dr. von Leyden, of Berlin. There will be a discussion on the Treatment of Chronic Articular Rheumatism (Dr. Bäumler, of Freiburg, and Dr. Ott, of Marieubad, reporters); on Epilepsy (Dr. Unverricht, of Magdeburg, reporter); and on Morbus Basedowii (Dr. Eulenburg, of Berlin, reporter).

TARTAR THERAPEUTICS.—A Tartar doctor, when he finds himself without his drugs and medicines, is not in the least embarrassed. He writes the names of the needed drugs on slips of paper, and these, being rolled up in little balls, are swallowed by the sick man. "To swallow the name of a remedy, or the remedy itself," say the Tartars, "comes to precisely the same thing."—*Noah Brooks*.

THE DISPENSARY ABUSE IN BERLIN.—The dispensary abuse is perhaps even greater in Germany, where private clinics compete with public for dispensary patients, than in this country. The Berlin correspondent of the *British Medical Journal* writes that "State interference with private clinics is the burning question of the day in Berlin medical circles, and that in the year 1895 more than 10,000 cases were treated in private clinics. The statistics for 1896 have not yet been published, but there is no doubt that there has been a considerable increase."

MEDICAL JOURNALS OF THE WORLD.—According to Professor Laboulbène of the Paris Faculty of Medicine, the total number of medical journals published in the world, which in 1880 was 785, had risen in 1895 to 1,380. There are 667 European medical journals, of which France has 190, Germany 168, Italy 140, Great Britain 101, Russia 86, and so on down to Turkey and Greece, which have only two each. America has 367, of which 343 are published in the United States, 4 in Canada, 17 in the Republics of South America, 2 in Mexico and 1 in Brazil. Twenty-five medical journals are published in India and 30 in China and Japan. Africa has only 2, and Oceania 3.

AN ANECDOTE OF LORD LISTER.—The following anecdote is related in the *London Daily News*: "While going round his wards in the Glasgow Royal Infirmary one day, Sir Joseph, then plain Mr. Lister, came to the bedside of a patient whose arm had been severely crushed without the skin having received any injury. Turning to the assembled students, he said, 'Gentlemen, I have frequently noticed that when severe injuries are received without the skin being broken, the cases nearly always recover. On the other hand, trouble is always apt to follow, even in trivial injuries, when a wound in the skin is present. How is this? I cannot help thinking that the man who is able to explain this problem will be one who will gain for himself undying fame.' " Lord Lister himself has proved the truth of his prophecy.

THE INVESTIGATION OF ALLEGED PLAGUE CASES IN CALCUTTA.—The Medical Board of Calcutta, according to the *Indian Medical Gazette*, have decided on clinical and bacteriological grounds that the cases reported as plague in that city proved on investigation to be either "ordinary non-venereal buboes or cases of simple enlarged glands, fever and bronchitis or intestinal obstruction!!" The exclamation points are those of the editor of the *Gazette*, who evidently does not believe that plague was certainly excluded in all the cases. As the editor remarks, the term "ordinary non-venereal buboes" is rather vague and does not satisfactorily account for the disease; and he points out the danger of overlooking the mild form of the disease, described as "pestis ambulans," which may at any time give rise to the severer type. The danger of minimizing the earlier manifestations of plague, on account of commercial considerations, has been brought out with sufficient vividness by the experience at Bombay, where the medical authorities refused to admit the presence of plague till it had gotten beyond their control. Whether Calcutta is to be taught as severe a lesson or not, the action of its medical board in denying the presence of the disease without the most careful and rigid examination is reprehensible in the highest degree.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, February 17, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 73, scarlet fever 39, measles 106, typhoid fever 13.

THE RHODE ISLAND HOSPITAL.—From the Report of the Board of Trustees of the Rhode Island Hospital, we learn that, during the year ending September 30, 1896, the number of patients treated was 2,283: males, 1,460; females, 823. The number during the previous year was 2,046. The total number of new cases treated in the out-patient departments was 7,306. The number of out-patients was smaller than that of the previous year, during which 8,649 cases

were treated, owing to the adoption of regulations by the trustees to prevent the abuse of the out-patient department by patients who were able to pay for medical attendance. A new building for contagious diseases was opened on June 13, 1896.

NEW YORK.

A FIRE AT ROOSEVELT HOSPITAL.—A fire, causing damage to the extent of \$15,000 or \$20,000, occurred on Saturday evening, February 13th, in what is known as the kitchen pavilion of Roosevelt Hospital. It is a two-story brick building with a mansard roof, the lower floor being mainly occupied by the boiler-room and store-rooms, and the upper floors with the sleeping apartments of laundresses, servants and porters. During the continuance of the fire, which is said to have been caused by a defective flue, and which, happily, was confined to the pavilion in which it originated, there was naturally considerable excitement among the patients of the hospital, but, through the energetic efforts of the superintendent and the house-staff a panic was averted.

A STUDY OF PLAGUE BACILLI.—Several weeks since Dr. H. T. Wilson, of the Hoagland Laboratory, received from China a supply of plague bacilli, and under the direction of the Brooklyn Board of Health has been making a series of experiments with cultures from them. His report on the results obtained is looked for with much interest.

THE OLDEST MALE IMMIGRANT.—Leon Reynolds, ninety-seven years of age, a native of Wexford, Ire., recently arrived from Southampton, and is said to be the oldest male immigrant on the records of the Immigration Bureau. His occupation is that of a saddler, and he expects to work at his trade in Illinois, where he has relatives living. The oldest immigrant on the books is Annie O'Neil, who arrived about a year ago, at the reputed age of one hundred and four.

Miscellaneous.

THE DEATH OF SIR SPENCER WELLS.

IN the death of Sir Spencer Wells, the medical profession has lost a man whose energy, activity and skill in the department of ovariectomy in its earlier days did much toward establishing it upon a firm footing, and resulted in an almost incalculable benefit to mankind in the relief of suffering and the saving of life. His recent death in the seventy-ninth year of his age, at Antibes, France, whither he had gone for change and rest, was sudden, though not entirely unexpected.

Thomas Spencer Wells was the eldest son of the late Mr. Wells of St. Albans, and was educated at Trinity College, Dublin. Thence he went to the Infirmary and School of Medicine at Leeds, and subsequently carried on his medical studies in the Anatomical School in Dublin, and at St. Thomas's Hospital. In 1841 he obtained his M.R.C.S. Eng., and three years later, he was elected one of the Honorary

Fellows called into being by the new charter. He subsequently entered as a surgeon in the Royal Navy, and on the outbreak of the Crimean War, he was appointed chief surgeon of the auxiliary hospitals at Smyrna and at Renkioi.

On returning to civil practice Mr. Spencer Wells distinguished himself by the success with which he practised the operation of ovariectomy, and by his eminent skill as a gynecologist. In 1865 he published the results of ten years' observation, both in private practice and as surgeon to the Samaritan Hospital for Women, and that volume was followed by others upon the same subjects in 1872 and 1882. A wider field was covered in 1885 by a book upon the "Diagnosis and Treatment of Abdominal Tumors," to which and to cognate subjects the author returned again and again at different dates down to 1891.

In 1882-83 Sir Spencer Wells was elected president of the Royal College of Surgeons of England. Dublin, Leyden, Charkof and Bologna conferred upon him the honorary degree of M.D., and a long list of learned societies at home and abroad offered their recognition of his eminence in the medical profession. In 1883 he received the honor of a baronetcy "in acknowledgment of the distinguished services which he had rendered to the medical profession and to humanity," a recognition of sterling merit which was universally appreciated throughout the profession.

PUERPERAL ECLAMPSIA; ITS ETIOLOGY AND TREATMENT.

DR. WILLIAM WARREN POTTER, of Buffalo, read a paper at the ninety-first annual meeting of the Medical Society of the State of New York, Albany, January 26, 1897, on the above subject.

He said, *inter alia*, that we seem to have arrived at the renaissance of eclamptic literature, that while the subject is being discussed in magazine articles and societies it would not answer for this society to keep silent.

Though the pathogenesis of eclampsia is still unsettled, we are certain that it is a condition *sui generis*, pertaining only to the puerperal state, and that to describe, as formerly, three varieties—hysterical, epileptic and apoplectic—is erroneous as to pathology and causation as well as misleading in treatment.

The kidney plays an important office in the economy of the eclamptic. If it fails to eliminate toxins, symptoms are promptly presented in the pregnant woman. Renal insufficiency is a usual accompaniment of the eclamptic state. Over-production of toxins and under-elimination by the kidney is a short route to an eclamptic seizure. However, many women with albuminuria escape eclampsia, and many eclamptics fail to exhibit albuminous urine.

The microbic theory of eclampsia has not yet been demonstrated. The toxic theory in the present state of our knowledge furnishes the best working hypothesis for prevention or cure.

Treatment should be classified into (a) preventive, and (b) curative. The preventive treatment should be subdivided into medicinal and hygienic; and the curative into medicinal and obstetric. A qualitative and quantitative analysis of the urine must be made at the onset. If there is defective elimination something

must be done speedily to correct a faulty relationship between nutrition and excretion. One of the surest ways to control progressive toxemia is to place the woman upon an exclusive milk diet. This will also serve to flush the kidneys and thus favor elimination. Distilled water is one of the best diuretics; it increases activity and supplies material—two important elements. In the pre-eclamptic state, when there is a full pulse with tendency to cyanosis, one good full bleeding may be permissible, but its repetition should be regarded with suspicion. If there is high arterial tension—vasomotor spasm—glonoin in full doses is valuable.

When eclampsia is fully established the first indication is to control the convulsions. Full chloroform anesthesia may serve a good purpose. If the convulsions are not promptly controlled the uterus must be speedily emptied. This constitutes the most important method of dealing with eclampsia. Two lives are at stake, and by addressing ourselves assiduously to speedy delivery of the fetus we contribute in the largest manner to the conservation of both.

Rapid dilatation first with steel dilators, if need be, then with manual stretching of the os and cervix, followed by the forceps, is the nearest approach to idealism. Only rarely can the deep incision of Dührssen be required. Cæsarean section should be reserved for extreme complications, as deformed pelvis, or to preserve the fetus when the mother's condition is hopeless. Veratrum viride is dangerous, uncertain and deceptive in action.

In eclampsia of pregnancy, that is, prior to term, the aseptic bougie, introduced into the fundus and coiled within the vagina, may be employed to induce labor. Finally, to promote elimination of toxic material, diuresis, catharsis, and diaphoresis should not be forgotten; neither should the hot-air bath, nor the hot pack be overlooked.

Correspondence.

CURIOUS STATEMENTS IN THE "LANCET."

PARIS, January 29, 1897.

MR. EDITOR: The following extracts from a paper written by Richard Brown, M.R.C.S., L.A.C., and which I find in the *London Lancet* for 1851, Vol. I, p. 8, offer such a curious comment upon the proof-reader if not upon the editor, of the *Lancet* of the date I have quoted, that I send them to you without further remark:

"On applying the ear or a stethoscope over the precordial region two sounds are heard following each other; the first is dull and prolonged, whilst the second is shorter and sharper. The first sound is produced by the diastole and the second during the systole of the ventricles; and in support of this theory I will state the circumstances under which this opinion was formed."

The writer concludes his explanation, for which I refer you readers to the article itself, by saying:

"I observed, moreover, that the first sound did not exceed the space in which the impulse was felt, but that the second sound was audible in nearly the whole extent of the chest, which would tend to strengthen the theory I have advanced, inasmuch as the sound produced by the diastole of the ventricle would be circumscribed, whereas, that produced by the systole would be diffused."

"I diagnosed ossification of the aortic semi-lunar valves and arch of the aorta, believing that during the production of the second sound (systole) the current of blood was passing in this direction."

Another remark of the writer is:

"Immediately followed the second sound produced by the onward current of blood through the aortic opening propelled by contraction of the ventricle."

After reading this remarkable paper, one involuntarily recalls a conundrum propounded most seriously by one lunatic to another: "Why is a mouse when it spins?" To which the satisfactory answer was: "The higher the fewer."

H. O.

METEOROLOGICAL RECORD

For the week ending February 6th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Date.	Baro- meter	Thermom- eter.			Relative humidity.		Direction of wind.		Velocity of wind.		Weath'r.		Rainfall in inches.
	Daily mean.	Daily mean.	Maximum.	Minimum.	8.00 A. M.	8.00 P. M.	Daily mean.	8.00 A. M.	8.00 P. M.	8.00 A. M.	8.00 P. M.

Newburyport	14,554	3	1	33.33	33.33	—	—	33.33	
Amesbury	10,920	—	—	—	—	—	—	—	

Deaths reported 3,120: under five years of age 743; principal infectious diseases (small-pox, measles, diphtheria and croup,

cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 297, acute lung diseases 612, consumption 369, diphtheria and croup 144, diarrheal diseases 56, typhoid fever 32, whooping-cough 17, scarlet fever 16, measles 11, cerebro-spinal meningitis 11, erysipelas 8, malarial fever 2.

From whooping-cough Philadelphia 7, New York 5, Chicago, Baltimore, Boston, and Washington 1 each. From scarlet fever New York 7, Boston 5, Chicago 3, Cambridge 1. From measles New York and Chicago 5 each, Boston 1. From cerebro-spinal meningitis New York 5, Boston 2, Washington, Worcester, Somerville, and Chelsea 1 each. From erysipelas New York and Chicago 2 each, Boston, Cleveland, Haverhill and North Adams 1 each.

In the thirty-three greater towns of England and Wales, with an estimated population of 10,992,524, for the week ending January 30th, the death-rate was 20.6. Deaths reported, 4,338; acute diseases of the respiratory organs (London) 355, whooping-cough 120, diphtheria 83, measles 58, scarlet fever 38, diarrhea 38, fever 29.

The death-rates ranged from 10.8 in Croydon to 33.6 in Plymouth: Birmingham 25.3, Blackburn 20.6, Bradford 21.0, Cardiff 18.1, Gateshead 16.0, Hull 16.2, Leeds 20.1, Leicester 16.1, Liverpool 25.7, London 19.9, Manchester 22.3, Newcastle-on-Tyne 20.4, Nottingham 21.7, Oldham 18.9, Portsmouth 16.3, Salford 25.7, Sheffield 19.4, Sunderland 19.8.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 6, 1897, TO FEBRUARY 12, 1897.

Leave of absence for two months with permission to go beyond sea, is granted MAJOR ROBERT M. O'REILLY, surgeon.

MAJOR JAMES C. MERRILL, surgeon, will be relieved from duty at Fort Sherman, Idaho, upon the arrival of FIRST-LIEUT. G. A. SKINNER, assistant surgeon, and ordered to report to the surgeon-general for duty. FIRST-LIEUT. GUY C. M. GODFREY, assistant surgeon, is relieved from duty at Fort D. A. Russell, Wyoming, and ordered to Fort Sheridan, Ill., for duty.

FIRST-LIEUT. FRANCIS A. WINTER, assistant surgeon, relieved from duty at Fort Grant, Ariz., and ordered to Washington, D.C., for examination as to his fitness for promotion.

FIRST-LIEUT. WILLIAM E. PURVIANCE, assistant surgeon, will proceed from Fort Columbus, N. Y., to Washington, D.C., and report for examination as to his fitness for promotion.

The following named medical officers will be relieved from duty at the Army Medical School, Washington, D.C., upon completion of the course about March 12, 1897, and ordered to take station as follows:

FIRST-LIEUT. BASIL H. DUTCHER, assistant surgeon, Fort Leavenworth, Kan.

FIRST-LIEUT. LEIGH A. FULLER, assistant surgeon, Fort Meade, S. D.

FIRST-LIEUT. FRANKLIN M. KEMP, assistant surgeon, Vancouver Barracks, Wash.

FIRST-LIEUT. GEORGE A. SKINNER, assistant surgeon, Fort Sherman, Id.

FIRST-LIEUT. CARL R. DARNALL, assistant surgeon, Fort Clark, Tex.

FIRST-LIEUT. WILLIAM E. RICHARDS, assistant surgeon, Fort Grant, Ariz.

FIRST-LIEUT. LOUIS P. SMITH, assistant surgeon, Fort D. A. Russell, Wy.

FIRST-LIEUT. MARSHALL M. CLOUD, assistant surgeon, Fort Sill, O. T.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE PERIOD FROM JANUARY 16 TO FEBRUARY 5, 1897.

BAILHACHE, P. H., surgeon. When relieved from duty at New York, N. Y., on or about March 1, 1897, to proceed to Washington, D.C., for duty. January 27, 1897.

PURVIANCE, GEORGE, surgeon. To be relieved from waiting orders February 20, 1897, then to proceed to Baltimore, Md., and assume command of Service. January 27, 1897.

HUTTON, W. H. H., surgeon. Granted leave of absence for five days from January 22, 1897. To proceed from Detroit, Mich., to San Francisco, Cal., in time to arrive there February 25, 1897, and assume command of Service. February 5, 1897.

STONER, G. W., surgeon. When relieved from duty at Baltimore, Md., on or about February 25, 1897, to proceed to New York, N. Y., and assume command of Service. January 27, 1897.

GODFREY, JOHN, surgeon. When relieved from duty at San Francisco, Cal., on or about February 25, 1897, to proceed to

Detroit, Mich., and assume command of Service. January 27, 1897.

IRWIN, Fairfax, surgeon. When relieved from duty at Washington, D. C., about March 5, 1897, to proceed to Philadelphia, Pa., and assume command of Service. February 5, 1897.

CARTER, H. R., surgeon. Granted leave of absence for seven days. January 19, 1897.

CARMICHAEL, D. A., surgeon. When relieved from duty at Vineyard Haven, Mass., on or about March 1, 1897, to proceed to Cleveland, O., and assume command of Service. February 5, 1897.

GLENNAN, A. H., passed assistant surgeon. To be relieved from duty at Reedy Island Quarantine Station April 5, 1897, then to proceed to St. Louis, Mo., and assume command of Service. January 27, 1897.

WOODWARD, R. M., passed assistant surgeon. When relieved from duty at Cleveland, O., on or about March 10, 1897, to proceed to Reedy Island Quarantine Station for duty, and to assume command of that station April 5, 1897. January 27, 1897.

VAUGHAN, G. F., passed assistant surgeon. To proceed from Philadelphia, Pa., to Washington, D. C., for duty. February 5, 1897.

BROWN, B. W., passed assistant surgeon. To proceed from Washington, D. C., to Charleston, S. C., in time to arrive there January 28, 1897, for temporary duty. January 19, 1897.

STEWART, W. J. S., passed assistant surgeon. To proceed from Washington, D. C., to Vineyard Haven, Mass., about March 1, 1897, and assume command of Service. February 5, 1897.

PROCHAZKA, EMIL, assistant surgeon. Order of January 5, 1897, directing him to report for examination revoked. January 20, 1897.

CUMMINS, H. S., assistant surgeon. When relieved from temporary duty at Southport Quarantine on or about January 30, 1897, to proceed to New York, N. Y., for duty. January 19, 1897.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, on Monday evening, February 22d, at 8 o'clock.

Dr. W. T. Porter will present a paper on "The Physiology of the Sympathetic Nerve."

Dr. G. W. Gay will read a paper on "Ligature of the funicular Artery." Discussion opened by Dr. H. L. Burrell.

JAMES G. MUMFORD, M.D., Secretary, 197 Beacon St.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The Section for Obstetrics and Diseases of Women will meet at 19 Boylston Place, Wednesday, February 24, 1897, at 8 P. M.

Dr. R. A. Kingman will read a paper on "A Case of Double-Ovariectomy During Pregnancy, the Labor Complicated by Uterine Inertia."

Dr. Edgar Garceau will read a paper on "Some Cases of Cystitis in Women."

F. W. JOHNSON, M.D., Chairman.

C. H. HARE, M.D., Secretary.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

PROF. WM. T. COUNCILMAN, will lecture on the evenings of Thursday, February 25th and Thursday, March 4th, at 8 P. M. Subject, "Arterio-Sclerosis." The profession are invited.

RECENT DEATHS.

HENRY BLANCHARD, M.D., M.M.F.S., died at Neponset, February 10, 1897, aged eighty-five years.

PERRY H. MILLARD, M.D., of St. Paul, Minn., dean of the College of Medicine and Surgery at the State University, died at Johns Hopkins Hospital in Baltimore, February 1st. He was graduated in medicine from Rush Medical College in 1872. He then spent several years in the practice of his profession at Stillwater, Minn., afterward removing to St. Paul. He was an aggressive advocate of higher medical education and it was mainly through his efforts that the present laws regulating the practice of medicine in Minnesota, were enacted.

NEPHRO-URETERECTOMY; RETROPERITONEAL EXTRAPATION OF A KIDNEY WITH ITS URETER.

BY J. W. ELLIOT, M.D.

THE patient, an unmarried woman, twenty-four years old, entered the Massachusetts General Hospital, March 24, 1896.

History.—She had been well and strong until three years previous to entrance, when she had an attack of acute articular rheumatism; for two years then she was not strong or well. One year before entrance she was attacked by severe abdominal pains and vomiting, for which she was taken to the Boston City Hospital and operated on for appendicitis; but the appendix was found to be normal. She remained at the hospital and the pains and vomiting continued. In June, 1895, Dr. Watson¹ made another abdominal incision for the purpose of palpating the kidneys. Having discovered a fluctuating area on the convex border of the right kidney, he did a lumbar nephrotomy, evacuating about two ounces of pus. The wound was allowed to heal in twenty-six days. Ten days later she complained of pain in both right and left kidneys, and Dr. Watson did a nephrotomy on both kidneys. The left kidney proved, however, to be healthy except for a cyst. The right side was much relieved by reopening the old sinus. She left the City Hospital in October, with a urinary fistula from the right kidney. After leaving the hospital she was unable to work on account of want of strength and the harassing condition of the urinary fistula. She applied to the City Hospital and elsewhere to have the kidney removed, but was advised against the operation.

When she entered the Massachusetts General Hospital she was weak and anemic, and suffering greatly from abdominal pains, which she declared to be the same as before her operations. She said, that being a servant by occupation, she would never be able to take a place while she had a disgusting urinary fistula, and that without employment she must go to the poor-house. She preferred to die than to continue as she was. Such a condition seemed to me to warrant her in taking the risk of a nephrectomy. We determined, however, to keep a record of the daily amount of urea in the fluid escaping from the fistula in the right kidney and in the urine as passed from the bladder, in order, if possible, to determine the relative value of the two kidneys. Catheterization of the ureters would have given us valuable information, but it was considered unwise on account of her bad general condition. We feared that the small amount of urea being eliminated might be made still smaller by any irritation to the urinary tract.

The fluid from the sinus was collected in a bottle by a soft rubber catheter fixed in the sinus.

A record was kept of the amount of urea eliminated for 17 days before the operation, during which time everything possible was done to improve the general health; and an improvement is clearly shown by the increased amount of urea eliminated. Dr. Cushing, the house-officer, made the admirable chart appended.

The average daily amount of urea found in the fluid from the sinus was $47\frac{1}{2}$ grains for the first five days,

and $48\frac{1}{2}$ grains for the last five days before the operation.

The average amount of urea passed from the bladder was 181 grains for the first five days and 294 for the last five days. The patient was then eliminating at her best, 342 grains of urea and one-seventh of this came from the sinus.

On April 13th, Professor Wood reported as follows:

"Fluid from sinus, specific gravity, 1.009; acid; albumin, .25 per cent.; large amount sediment, chiefly pus and small round cells, some of which were fatty. Few large hyaline casts from dilated tubules, with pus corpuscles and renal cells adherent. Very few blood globules. Urea, .94 per cent. The urine had a specific gravity of 1.026; albumin, slight possible trace; sediment, cells from vagina and vulva; excess of leucocytes. Few blood globules, small cells. An occasional hyaline and granular cast. Urea, 2.44 per cent.

From all this it seemed probable, first, that all the urine from the right kidney came through the sinus, because the fluid was opaque with pus, while little or no pus was found in the urine, also because the urea from the sinus remained nearly constant while the urea in the urine varied considerably; second, the left kidney was in fairly good condition, and only one-seventh of the urea came from the right side.

The patient's general condition improved, yet morphia was occasionally required for the pain in her right side.

Operation, April 17th. I removed the right kidney, with the old sinus and a greater part of the much enlarged and thickened ureter. The incision extended obliquely forward from the erector spine and the twelfth rib to the middle of the crest of the ileum. This was afterwards continued past the anterior superior spine and down on to the abdomen, $11\frac{1}{2}$ inches long in all. After a tedious dissection in the cicatricial tissue caused by the previous operations and disease, the kidney was freed and the vessels tied. It was then noticed that the ureter was very thick and as large as a man's thumb. The peritoneum and its contents being retracted inwards, the ureter was dissected from its bed down into the pelvis. The kidney with a few inches of ureter, was then cut away to allow an examination of the inside of the ureter. A finger-tip could be passed into the cut end, which did not collapse but stood open on account of its thickened walls. A sound was then passed down the ureter into the bladder; and although no obstruction was met, yet I got the impression that the ureter had been blocked with inspissated pus and epithelium. Upon farther examination it was discovered that the ureter became nearly normal in size and consistency soon after passing the pelvic brim; consequently it was cut at that point. The end was closed by stitching the mucous membrane with animal tendon, this was covered by turning down a circular cuff as in appendectomy, which was stitched with silk. The operation was done wholly extra-peritoneally, but the peritoneum was accidentally opened twice and closed with a ligature. The wound surface was enormous, but the muscles were easily reunited with stitches; a gauze drain was left from the cut end of the ureter to the wound in the back. The specimen showed a uretero-pyelonephritis. This was probably caused by a stone which had disappeared. The operation was well borne. A permanent catheter was placed in the bladder, to avoid

¹ Boston Medical and Surgical Journal, June, 1896.

the possibility of back pressure on the cut end of ureter. First twenty-four hours, urine 5xx.

On April 21st, four days after operation, only a very small amount of urine was passed. The patient looked badly, was restless, but was dull and recognized no one. One-eighth of a grain of pilocarpine caused profuse perspiration, but no change in appearance. Hot-air bath and copious watery stools (due to calomel) brought about an improvement in her general condition.

April 22d. Amount of urine still very small. Patient vomiting and in a critical condition. Pilocarpine and hot-air baths again brought about an improvement. I have supposed that this uremic condition was caused by the irritation of the catheter. Then came a slow but steady gain and a complete convalescence. The greater part of the wound healed well, but the tissue in the region of the old sinus suppurated for several weeks, and finally healed.

The patient was shown at the Surgical Section on December 2d, seven months after the operation. She stated that she was working hard as "second girl," in a family of five people; that she felt perfectly well, better than for the last three years. She looked the picture of health.

In looking over the table showing the daily amount of urea excreted, it is interesting to note that the average daily amount excreted in the first five days of the second week after the operation was 340 grains. Thus, at the beginning of the second week after the operation, which was severe and followed by a critical illness, we find the remaining kidney secreting as much urea as both were doing in comparatively good health just before the operation. Moreover, the average amount of urea for five days, five weeks after the operation, was 405 grains, an amount greatly exceeding anything that both kidneys had ever done while under observation. These facts suggest caution in

CHART OF THE DAILY AMOUNT OF UREA BEFORE AND AFTER NEPHRECTOMY.

accepting the dictum of the so-called "conservative renal surgery," that any part even of a diseased kidney should be left if possible.

My own opinion is that one good kidney works better alone than when combined with another diseased kidney. The explanation of these facts which occurs to me is that the diseased organ, by some reflex irritation, prevents the other kidney from making the compensatory hypertrophy which it can and does make as soon as the disease is removed.

The only cases of nephro-ureterectomy I have been able to find in the literature are reported by Kelly in the *Johns Hopkins Bulletin* for February and March, 1896. Kelly reports three cases of his own, and refers to one other. They were all done in different ways, and were all successful. The first case was done by a laparotomy, transperitoneal. The second case was a retroperitoneal operation by a long lumbar incision, like the one here reported. The third case was also retroperitoneal, by a short lumbar incision, and a vaginal incision through which the lower end of the ureter was removed. The case referred to was reported by Dr. Reynier, February 24, 1893, in *La Semaine Médicale*. The patient, a man twenty years old, had his kidney removed April 27, 1892, for uretero-pyelo-nephritis. At a later date, five inches of the ureter were removed by enlarging the lumbar incision. The patient not being cured, an effort was made, without success, to reach the lower end by a para-rectal incision. Later, the lower portion was removed by an incision parallel to the inguinal canal. Result good.

HERNIA EPIGASTRICA, WITH A REPORT OF CASES.

BY HOWARD A. LOTHROP, A.M., M.D.,
Assistant in Anatomy, Harvard University.

OF the numerous varieties of hernia, probably none are more obscure, and at the same time so frequently the source of severe and prolonged suffering, as hernia epigastrica. The physical signs are often so meagre, and the subjective symptoms so prominent and suggestive of some lesion of the stomach, that the true etiology is easily overlooked. The following cases will serve as examples:

CASE I. This patient is a girl, sixteen years of age. Her family history is negative, and she has always enjoyed good health. From early childhood she has been accustomed to an active out-of-door life, and for two years she has been a *danseuse* in a travelling company. Her joints are exceedingly supple, and she can over-extend the trunk, so that the occiput touches her heels. In performing this latter feat, almost a year ago, she experienced a sudden epigastric pain, accompanied by no other symptoms, and ever since then she has had a tender spot in that area. She has been unable to continue this occupation on account of this local pain.

Six months ago, she perceived a small swelling just below the xiphoid cartilage, tender to touch, and occasionally the seat of sharp, shooting pains; its presence has been constant, and its size has slowly increased. Aside from these symptoms, her general health has been good, except for occasional gastric disturbances lasting a few days. These gastric "crises" come on independent of diet, but are associated with

augmented epigastric pain and tenderness in the vicinity of the tumor.

During one of these gastric "crises," I saw her for the first time. She was confined to her bed, suffering from nausea, occasional vomiting, and general abdominal pain. She knew of no cause for these symptoms, but directed my attention to the swelling below the xiphoid cartilage. She was fairly well developed and nourished, but was anemic. Physical examination was negative, except for the presence of this tumor, which was about half as large as an English walnut, located in the median line, directly below the cartilage, so as to obscure its lower extremity anteriorly. The skin was normal and not adherent over the tumor which was painful to the touch. The tumor, however, was only slightly movable, but could be plainly differentiated from the cartilage above it; its surface was perfectly smooth, and the mass gave the sensation of fluid or fat when palpated. There was a distinct impulse on cough, both on inspection and to touch. When the recti muscles were made tense, the tumor became more prominent, and was evidently anterior to the broad tendons composing the *linea alba*, but by no means could it be reduced. The case was considered to be one of irreducible epigastric hernia, containing either subperitoneal fat, or omentum, or both. Dr. M. H. Richardsou was kind enough to see her with me at this time, and he concurred in the probable diagnosis, and advised an exploratory incision. Operation was refused, however, by the parents.

Unwilling to lose sight of the patient, palliative measures were resorted to, and the case carefully studied for three months. During this interim, the physical signs remained the same except that the tumor doubled in size; the gastric symptoms (eructations, nausea, occasional vomiting and pain) came and went at irregular intervals, provoked particularly by overexertion, while the diet had less influence in provoking the attacks. The greatest relief was obtained at such times by absolute rest in bed.

Meanwhile the patient began to suffer from pain in both feet and in the tibiae, as well as from obstinate headache. There appeared a small fluctuating tumor over the right supra-orbital ridge, and two small indolent ulcers near the left knee. The anemia increased, and the general condition of the patient became worse. Although no history could be obtained, these conditions were diagnosed as tertiary syphilis and yielded promptly to treatment later. At this time consent of the parents for operation was obtained, and accepted with some anxiety as regards the outcome of the wound, on account of the active nature of the syphilis.

Operation. — Under the influence of profound anesthesia, a three-inch vertical incision was made over the tumor, and carried through the subcutaneous fat layer to reach the sac. On carefully isolating the tumor it was found to consist mostly of a thick fat layer surmounting a layer of connective tissue which continued from the base of the tumor as a pedicle and passed through an oblique slit in the *linea alba* just to the left of the median line. While dissecting around this tumor, outside of what proved to be the sac, about a drachm of thick turbid fluid escaped, having the general appearance of pus. Fearful lest the abdomen should become infected, the tumor was carefully drawn out of the wound, and the pedicle ligated as

deeply as possible. The stump retracted within the ring, which was oval in shape, with a long diameter of about a quarter of an inch, situated just at the left of the linea alba, and directed upwards and outwards. The tumor and fluid were located anterior to the external abdominal aponeurosis, and the pedicle extended through all of the tendons of the broad abdominal muscles, and on section of the excised fat mass, it was found to contain a prolongation from the peritoneum. The wound was carefully irrigated with corrosive sublimate and peroxide of hydrogen on account of unexpected escape of what resembled pus. Further exploration was not considered advisable, and the ring was closed on the transverse with catgut, and the edges of the skin approximated with interrupted silkworm-gut sutures deeply placed, so as to coapt all parts of the wound.

The convalescence was uninterrupted. Eight months have elapsed since the operation, without recurrence either of the hernia or the subjective symptoms. A careful examination of the excised portion, showed that it was a mass of subperitoneal fat surrounding a protruding funnel of peritoneum. Under anti-syphilitic treatment, the tertiary lesions disappeared.

The conclusion arrived at, on considering this case, was that we had to do with a tumor, consisting of subperitoneal fat, in the centre of which was a sac of peritoneum which communicated with the general abdominal cavity—a condition commonly preceding the appearance of omentum or intestine in such cases. Furthermore, that the case was complicated by the presence of a small gumma, which interferred in no way with the primary union of the wound.

CASE II was a patient of Dr. J. W. Elliot, who kindly allowed me to study it and report the following account. The patient was a man, fifty-eight years of age, whose family history is negative. He was a rugged boy, and grew to manhood without suffering any serious illness.

When eighteen years of age he fell upon a sharp-pointed stick, receiving a painful injury in the epigastrium, with consequent symptoms of collapse on account of the severity of the fall. For some weeks he suffered local pain, which gradually wore away. Six years later, he began to experience sharp pain in the epigastrium, particularly after eating, together with gastric symptoms of varying severity, at times sufficient to interfere with his occupation as a farmer. For ten years from this time, he suffered from moderate gastric symptoms, accompanied by tenderness and pain in the epigastrium, none of which yielded to internal medication.

Twenty years ago, the attacks of pain and vomiting became more frequent and severe, and he noticed for the first time a small tender swelling above the umbilicus. This tumor increased gradually for five years, when he says that it was at times as large as his fist, but has always been more or less reducible. For the last fifteen years, its size has not changed materially. The attacks of pain and vomiting were always coincident with the appearance of the tumor, and were alleviated on its reduction. The patient soon learned to appreciate this, and he wore an abdominal swathe to hold back the tumor, but did not succeed perfectly by this means. As a result, he always had some epigastric tenderness, and more or less distress after eating. The hernia frequently appeared during his work in the fields, accompanied by severe pain, and his method for

reducing it was to lean over a fence-rail and thus force it back, a procedure generally successful, and then the pain and vomiting would disappear. At other times he would lie on his back, and reduce it himself by taxis.

About fifteen years ago, the attacks assumed a new phase. In addition to the pain and gastric symptoms, coincident with the appearance of the hernia, the attack would be preceded by a chill, followed by considerable elevation of temperature, and on the following day a very marked degree of jaundice would appear. There was no periodicity in these attacks, which were rarely more frequent than once a week, and occasionally an interval of three months would elapse, provided the hernia was retained in position. Meanwhile there persisted the usual dull ache with occasional sharp pain in the epigastrium, and the distress after eating.

Several physicians in attendance during the acute attacks had made a diagnosis of gall-stones, but none have ever been found. The stools were clay-colored, and the urine and tissues tinged with bile pigment, following the acute epigastric pain. It is important to note that the hernia was generally as large as ever during the attack, and then it could be reduced only with difficulty.

He has suffered from fewer severe attacks during the last five years, but otherwise there has been no improvement in his condition. His appetite is fair and his bowels generally constipated. During the last two years his weight has fallen from 245 to 165 pounds. Heavy work, sudden jolting, and hearty meals aggravate his symptoms. Generally of a happy frame of mind, he has become worried and fretful of late. Following one of these acute attacks, he consulted Dr. J. M. Jackson, who considered the case to be of a surgical nature, and he was referred to the Massachusetts General Hospital, where I saw him for the first time.

Physical Examination.—The patient is a large man, fairly well nourished. While lying on his back, inspection showed nothing abnormal, except a little fullness of the skin in the median line half-way between the xiphoid cartilage and the umbilicus. This became more prominent momentarily on coughing, but remained persistently more prominent when lying on his abdomen or during prolonged straining, even while standing or sitting. When fully protruded the mass was about the size of a hen's egg, lobulated, soft and movable in all directions from a fixed point just to the left of the linea alba. Here was a transverse oval opening which would just admit the tip of the index finger. The mass could be reduced except a small portion which was adherent near the ring. At the time of examination, there was no local pain, but some tenderness. The abdomen was not distended, and palpation and percussion did not reveal any abnormality of the abdominal viscera. Aside from a few scars, the result of injuries, and a considerable amount of vitiligo, physical examination was negative.

Urinary Examination.—Acid; specific gravity, 1.022; pale; albumin, one-tenth per cent.; sugar and bile pigment absent; sediment was slight in amount, consisting of fine granular and hyaline casts of large diameter, medium and small round cells.

Operation. under ether narcosis, by Dr. J. W. Elliot. A three-inch vertical incision was made over the tumor, passing through the integument and subcu-

taneous fat layer, when the fibrous sac of the tumor presented. This was carefully isolated on all sides down to its pedicle, and then opened. Within appeared a portion of the omentum, adherent just to the left of the ring, so that only a small part remained irreducible. The adhesion was transfixed and ligated. The sac with its contents was in a plane anterior to the external abdominal aponeurosis. The ring was nearly circular with smooth edges, and just admitted the tip of the index finger. This opening was enlarged vertically in both directions in order to admit the hand for examination of the liver, gall-bladder and ducts; no abnormality was detected. Around the whole inner circumference of the ring, however, the omentum was firmly adherent and continued inward toward the pyloric end of the stomach (great omentum) and then to the liver (lesser omentum) as a fairly firm band. On severing this from the ring, it was found to contain the round ligament of the liver (obliterated umbilical vein) and a portion of the falciform ligament and great omentum. All omental adhesions were freed, and redundant portions of the omentum excised, as well as the edges of the ring, so that the entire sac was removed.

The wound was closed by means of interrupted silkworm-gut sutures, which passed through all of the layers of the abdominal wall, but before these were ligated, the various layers were respectively united by continuous silk sutures. Primary union resulted.

The convalescence was practically uninterrupted for two weeks, when the patient had a chill, followed by a sudden rise of temperature which lasted about forty-eight hours, and then a marked degree of jaundice appeared. Careful examination of the blood at different periods was negative as regards the presence of any plasmodium of malaria. The patient was given quinine, which he has continued to use off and on ever since. It is now seven months since the operation and he has had no recurrence of chills, jaundice or attacks of pain in the epigastrium; all tenderness disappeared and his digestion is greatly improved. He is able to do as much work as ever. About five months ago he had edema of both legs, which lasted a short time, and has had some dyspepsia ever since at intervals. This edema was probably of renal origin, and this may be the source of his dyspepsia. He states that he is entirely relieved of all his old symptoms and only regrets that he was not operated upon twenty years ago.

CASE III was that of a woman fifty years of age. She was a patient of Dr. M. H. Richardson, and to him I am indebted for these notes and for the privilege of reporting this case.

She is a married woman, has given birth to several children, and, up to the time of the onset of the present trouble, has enjoyed good health. Twenty-four years ago, following soon after the birth of a child, there appeared a small tumor in the linea alba about three inches above the umbilicus. Just perceptible at first, this tumor slowly enlarged until it reached the size of a large orange, some year or more ago. It has always been more or less reducible until five days ago, and the patient has been able to retain it fairly well by means of mechanical devices. During all of this long period, there has always existed a varying degree of tenderness in the epigastrium, more severe when the tumor was not reduced.

At periods, coinciding with the greater prominence of the tumor, a certain group of symptoms invariably

appeared. There was increased local tenderness, together with pain, which radiated in all directions, particularly around the sides to the back, where there was "dragging and backache"; also a group of symptoms referable to the stomach, such as anorexia, nausea and occasional vomiting. At such times, there was a general feeling of malaise, and the patient learned that the greatest relief was obtained by rest in bed, and also perceived that the tumor disappeared when she was lying on her back. For years she suffered from what she termed "dyspepsia," and all of her symptoms were worse after a hearty meal.

Always more or less of an invalid for over fifteen years, she managed to get along with only palliative measures until five days ago, when the tumor became irreducible, with the consequent persistence of the usual acute symptoms. She was then seen by Dr. Richardson for the first time, and her condition was as follows: In addition to the above subjective symptoms, there presented a tumor the size of a large orange, located in the median line three inches above the umbilicus. The skin was normal and movable over a tender mass which in turn was lobulated and movable over the tense abdominal muscles, but was apparently fixed by a pedicle, located near the median line. A diagnosis was made of incarcerated omental hernia in the linea alba, and operative measures were decided upon as the only means of relief. A vertical incision exposed the sac which was freed on all sides as far as the base and then opened. The contents consisted of masses of omentum which were carefully excised and the pedicle returned to the abdominal cavity. The sac was freed deep within the ring, ligatured at its base, and the distal portion excised. The muscular and aponeurotic layers were held in approximation by interrupted silk sutures, and the wound tightly closed with interrupted sutures of silkworm gut, which included all the layers of the abdominal wall. The wound healed without complication.

Relief from all symptoms was immediate after the operation, and remained so for some time. Of late, however, she has had some gastric disturbance which may be attributed either to adhesions (to be considered later) or to a chronic catarrhal gastritis consequent on so many years of disturbance in that organ.

CASE IV was that of a woman, sixty years of age, kindly referred to me by Dr. R. W. Greenleaf, to whom she had presented herself on account of gastrointestinal symptoms. On physical examination, Dr. Greenleaf had detected a small and slightly tender tumor in the epigastric area, and considered the case to be of surgical as well as of medical importance.

She had been married, was the mother of several children, and had always been a well woman, except for occasional gastric disturbances during the last year. Particularly during the last six months, she has had distress after eating, manifested by a sense of weight in the epigastrium, local pain on moving about, eructations, nausea and occasional vomiting. Her bowels are generally constipated, and she suffers from headache.

Examination revealed a well-developed and well-nourished woman. In the epigastric area, half-way from the costiform cartilage to the umbilicus, and between the bellies of the recti muscles, was a smooth rounded mass, with distinct outlines, and about as large as a cherry. It was slightly tender on deep pressure, and remained irreducible, although movable somewhat from side to

side; its consistency was that of fat tissue. Notwithstanding the presence of local tenderness for some months, the patient had never detected the presence of this tumor, and of course was ignorant of any etiological factor.

Her case was studied for three weeks. The objective symptoms never varied, but subjectively her condition improved on liquid diet and absolute rest, only to relapse again after exertion, or the ingestion of ordinary articles of food. She feared the risk of operation, and her case was lost sight of. As will be explained later, this tumor was probably a mass of fat, derived either from the subperitoneal fat layer or from the omentum, and possibly both may enter into its formation.

Since reporting the above cases, Dr. Richardson has given me these brief notes of two further examples:

CASE V was that of a man who had observed a small tumor in the epigastrium for three years with more or less discomfort arising therefrom. Operation revealed the presence of a small omental tumor about two inches above the umbilicus near the median line. Relief was immediate and permanent after this procedure.

CASE VI. A man, forty-three years of age, with excessive panniculus adiposus. He had observed a small tumor just below the ribs for four years, but suffered no inconvenience until a short time ago, when it became tender and painful. Examination revealed a tumor, size of an English walnut, to the left of the median line just under the edge of the costal cartilages, presenting the appearance of a lipoma. There is a slight impulse on cough. This is probably an omental hernia, and is to be operated on shortly.

Under the class "*Hernia Epigastrica*," we include all herniæ which appear in the area limited above by the xiphoid cartilage, below by the umbilicus, and laterally by the costal cartilages. In that they commonly appear in the linea alba, they have been called "*Herniæ in the linea alba*," which would include the very rare cases occurring below the umbilicus, not consequent on a laparotomy. The former term seems to be preferable, both on account of the character of the symptoms, and the area included.

In 1743 Garengot described these cases under the name of "*Gastrocele*," believing that the stomach was the organ present within the sac. Over a hundred years ago, A. G. Richter described similar cases, but he declared that the stomach never became involved. In 1802 Maunoir performed the first successful operation, but previous to Terrier's publications in 1886, operation was strongly advised against on account of the dangers of peritonitis, which often resulted after such operations. In recent years, valuable contributions have been added by Czerny, König, Witzel, v. Bergmann, and Lucas-Championnière. This variety of hernia is of unusual occurrence, but undoubtedly many cases pass unrecognized. In a series of 16,800 cases of hernia of all varieties, examined personally by Berger, he found 137 cases of *hernia epigastrica*, either occurring singly or in complication with other varieties.

Age.—This is a variety of hernia peculiar to adult life. It is exceptional to find these cases below eighteen years of age, and the great majority are between twenty-five and fifty. Two cases of congenital origin have been recorded by Sir Astley Cooper, and

a very few cases are reported as arising during early childhood.

Sex.—In a series of 202 cases, 178 were males and 24 were females. The majority of these belonged to the working classes.

Etiology.—The history of the great majority of these cases is that of an insidious onset, and the attention of both patient and physician is directed to the stomach, at a period either before the hernia has made its appearance externally, or is too small to be observed on casual examination. On the other hand, however, there are numerous authentic cases where all symptoms have been preceded by a definite trauma followed by very acute local and general symptoms, and the appearance of a tumor within a few hours.

The following classification of cases has been suggested by Roth:

(1) Embryological defect due to failure of the abdominal parietes to close in the median line. This is an exceedingly rare condition, of which Sir Astley Cooper has reported two examples.

(2) Congenital or acquired thinness of the abdominal fasciæ, also an unusual cause of herniæ, although frequently resulting in marked diastasis and circumscribed prominence of the abdominal parietes.

(3) A theory suggested by J. Cloquet and elaborated by Witzel and others, whereby for some reason or other, a small slit occurs in the fascia into which the subperitoneal fat makes its way, followed in turn by a pocket of peritoneum with the eventual entrance of omentum or intestine. Innumerable examples (in different stages) render this supposition very plausible. (Cases I and II, also one in particular cited by Witzel, where there were three epigastric herniæ in one patient representing different stages. One contained subperitoneal fat *plus* a fold of peritoneum, a second with the addition of omentum, and a third with intestine.)

This subject will be considered in detail under Pathological Anatomy.

(4) Trauma is an undoubted cause of these herniæ. Although some weeks may elapse before the appearance of an external tumor, there are numerous cases where the hernia has developed in a few hours with the usual accompanying symptoms. The rent in the aponeurosis may be the result of:

(a) Direct blow on the epigastrium: (1) Falling on to more or less sharp projections (Case II); (2) Blows by flying missiles.

(b) Sudden vertical tension on the abdominal muscles: (1) Internal origin—coughing, vomiting, etc.; (2) External origin—heavy lifting or pulling, especially with the arms elevated and the trunk extended (Case I).

Undoubtedly trauma frequently makes possible the early steps to be described as taking place in the incipient acquired variety. Heredity seems to play no rôle, and although epigastric herniæ are frequently complicated by other varieties, there does not seem to be any common underlying cause or predisposition.

(To be continued.)

COCAINE has been declining in price very rapidly of late, owing to heavy shipments of the leaves of the *Erythroxylon coca* plant from Peru and Bolivia. The drug is now quoted at \$2.50 an ounce. A few weeks ago it was nearly \$4 an ounce.

AIR-EMBOLISM, WITH REPORT OF CASES, CLINICAL AND EXPERIMENTAL.¹

BY JAY PERKINS, M.D.,

Medical Examiner, District No. 10, Providence County, R. I., Pathologist Rhode Island Hospital.

(Concluded from No. 7, p. 156.)

THE two following cases came under the observation of Dr. W. H. Palmer, in his official capacity as medical examiner, and I now report them with his kind permission.

CASE I. A. H., married, twenty-eight, pregnant in the fifth month. Found dead in a physician's office. Body found lying on the floor in the early evening. The physician said that she came to his office to procure some medicine for a cold, and while standing by the door opening into his consulting-room fell dead upon the floor. Body viewed while still warm, and was found probably pregnant, with watery blood in the vagina. No sign of violence observed. Autopsy held the following morning. Weather cold; no decomposition present. Body well nourished, and evidently healthy in life. As the pectoral muscles were reflected, air bubbles escaped from the intercostal vessels. The organs of the chest were normal in position and size excepting that the right side of the heart was very full. The uterus contained a fetus in the fifth month. Placenta on the right side of the uterus in normal position. A large amount of blood in soft clots was found in the uterine cavity, and had evidently come from the placenta, which was torn up two or three inches, opening the uterine sinuses. The membranes were intact. Air was found in the internal iliac vein, ascending vena cava and heart, the heart also containing frothy blood. The other organs were normal. Death was caused by the opening of the uterine sinuses in an attempt to induce an abortion.

CASE II. C. F., unmarried, second child, was found dead in a physician's office, February 29, 1896, at about 8.30 A. M. The physician said that the patient came to his office in the morning before he was dressed; that she complained of pain in the region of the heart and of difficulty in breathing. He seated her on the edge of his gynecological table to examine her, and she fainted. He tried to revive her but without success. When first viewed in the office, there was no blood on the external genitals, but some bloody water in the vagina. An autopsy was held in the evening at which the writer was one of the witnesses. Autopsy twelve hours after death. Weather cold; no decomposition present. The face indicated pain, the eyes were sunken, and the lips were drawn over the teeth. The pupils were widely dilated. There were *then* stains, such as would be made by watery blood, about the external genitals. There were a few similar stains on the clothing which were not present when the body was first seen in the morning. There was a dirty stain on the skirt, which was made by some liquid which caused stiffening, and upon an examination with a microscope this showed epithelial cells in abundance. On section through the pectoral muscles frothy blood escaped from some of the intercostal vessels. The heart was distended; the vessels leading to and from the heart were ligated, and the heart opened under water, large bubbles of air and a very little frothy blood rising to the surface. The left side contained a little frothy blood. Air was seen

in the ascending vena cava, and was found later in the vessels of the brain. Though, as pointed out by Dr. Draper, air might be drawn into the vessels of the brain while removing the calvarium. I have never seen this appearance in any other case. The other organs were normal, though the kidneys were somewhat injected, excepting the uterus. The uterus extended to about the umbilicus; the os uteri was very patulous. The amniotic sack contained upwards of 250 c. c. of liquor amnii and about 40 c. c. of air. Just inside the cervix there was a small amount of clotted blood. On the membrane there was an abrasion resembling a scratch by some blunt instrument. The placenta was attached low down on the left side, and was separated from the uterine wall at its lower part. The laceration extended into the uterine sinuses and by a puncture into the amniotic sack. The opening into the amniotic sack had an average diameter of five millimetres. From the internal os to the edge of the placenta was three centimetres. The amniotic sack also contained a fetus of six to seven months in gestation.

When a blood-vessel is opened we usually have a hemorrhage. How is it in these cases we get air flowing in instead of blood coming out?

When the veins of the neck are cut, air is drawn in by suction through the negative pressure in the chest during inspiration. The stronger the inspiration the more air sucked in, and the entrance of the first air causes struggling and violent respiratory action. This accident was more common before the use of anesthetics than now, because of the tension of the respiratory muscles during an operation. The pain acted as a stimulus, causing a strained or forceful respiration. The uterus is so far removed from the chest that it does not seem as if the act of inspiration could have as much effect here as in the veins about the neck. But during pregnancy and especially advanced pregnancy the uterine veins are so large and so directly connected with the vena cava that we probably get considerable suction in this manner during forced or gasping inspiration; but before this suction can draw air into the heart, it must get into the uterus.

The uterus being composed of involuntary muscle fibres, naturally contracts whenever stimulated, and especially is this true of the pregnant or parturient uterus. Any foreign body in the uterus causes it to contract; also it contracts from reflex causes—as a new-born babe nursing will increase the after-pains. Each contraction is followed by a relaxation, and the more forceful the contraction the more pronounced the relaxation; and being a hollow organ there is a tendency to a vacuum when relaxation occurs. Normally the soft parts below the uterus close in so as to prevent the entrance of any foreign medium, as air, during this relaxation. But if from any cause the soft parts do not close in, air may enter. This complete closure may be prevented by the position of the patient, especially by separation of the legs, as was probably the case in the patient who remained standing during the birth of her child; also by certain movements of the body, as by raising the head and shoulders. But in many cases, and probably a great many we know nothing about, the air enters through or around an instrument used for legitimate or illegitimate purposes, for giving a douche or bringing on an abortion. The air having gotten into the uterus the rest is easily accounted for in cases where the acci-

¹ Read before the Rhode Island Medico-Legal Society, June, 1896.

dent occurs before the sinuses have become closed by clots.

We have in the action of the uterus a counterpart of the diaphragm in carrying on absorption from the peritoneal cavity. The diaphragm contains numerous lymph-spaces; during relaxation these fill with any fluid within their reach in the abdominal cavity, and then when it contracts this fluid is forced on into the lymph-vessels. The uterine wall at the placental site contains many large sinuses; at full term some of them are large enough to admit the little finger. After the separation of the placenta, these are normally closed by the contraction of the uterus and by clots; but during the relaxed condition of the uterus, especially when it is still distended with the fetus, we have the mouths of the sinuses remaining open, and usually hemorrhage will take place, but if air is present in the uterine cavity the forcing of it into the sinuses will prevent hemorrhage and fill the sinuses with air. Then when the uterus again contracts, or in consequence of the force still applied, if a syringe is used, all of the air is forced from the sinuses into the veins and so to the heart, being assisted by the suction towards the chest during inspiration.

In the case of C. F. (II) there was a low attachment of the placenta. And in the trial of the physician in whose office she died the witnesses of the prosecution maintained that probably a curved instrument was used to puncture the membranes and draw off the water; that this instrument was passed up until it reached or punctured the placenta, was then turned with the point towards the membranes and forced into the amniotic sack. In going through the membranes it tore the lower edge of the placenta from the uterine wall, opened the entrances to several uterine sinuses, and air rushing in around the instrument, or through it, if hollow, before it got into the amniotic sack prevented hemorrhage.

There is one more interesting point in this case. How did the air get into the amniotic sack? The only explanation I can find is the tendency of the pregnant uterus to contract under even slight stimulation. When the instrument was introduced, a contraction of the uterus took place, forcing the blood out of the sinuses; this contraction was followed by a relaxation, during which air was drawn into the uterus. It was a cold morning; the air getting into the uterus expanded by reason of increased temperature, entered the uterine sinuses, acted as a foreign body, and assisted the action of the instrument to bring on another contraction of the uterus; this contraction forced more air into the vessels of the uterus and some into the amniotic sack.

The immediate cause of death in consequence of air in the blood-vessels is given by different authors as one of the three following ways:

(1) Paralysis of the heart from overdilatation of the right ventricle.

(2) Air in vessels of the brain, causing ischemia.

(3) Obstruction of the pulmonary circulation by bubbles of air in the capillaries of the lung, causing death from asphyxia.

The symptoms of air in the veins depends on the amount introduced, the rapidity and force with which it is introduced, and the relative strength of the heart into which it is introduced. A small amount can be taken care of by the blood without causing symptoms; a larger amount, but still not enough to kill, will

cause immediate temporary irregularity of respiration and of the heart's action, a sensation of impending death, a cry, a convulsion, or simply a collapse. On listening over the heart a churning sound is heard. If the air enters more slowly, we may get air-embolism of the pulmonary vessels and death from asphyxia, or later from pneumonia. The plugging of the pulmonary vessels causes deeper inspirations, through the need of the system for more oxygen, and thus more air is drawn into the vessels. Air can, however, pass through the capillaries, if only there is sufficient force behind it, as Professor Senn has shown by injecting air into the arteries of dogs. He found that by injecting air into the arteries he got "convulsions, coma, tetanic rigidity of the limbs and extensor muscles of the back. If the animal does not succumb to the primary effects of the air upon the brain and medulla oblongata, a series of symptoms succeed which announce the arrival of the blood in the veins and right side of the heart." Death takes place from asphyxia from the plugging of the pulmonary capillaries with frothy blood, the right side of the heart being less strong than the left. If a large amount of air enters the blood-vessels at once, we have only momentary symptoms—the cry, deep respirations and death, or simply death. The action being nearly or quite wholly on the heart. Here the symptoms do not last long enough to be due to non-aëration of the blood and there are no brain symptoms unless, as occasionally occurs, we have a convulsion. If the chest is opened immediately after death, the right auricle will be found still contracting, the left auricle and both ventricles having ceased action. If, however, a puncture be made in the right side of the heart and the air let out, the heart will begin to contract again. In dogs dying from the spontaneous entry of air into the jugular vein death is more prolonged and the heart continues to beat for some time after apparent death has taken place.

The first four of the following experiments were carried out under adverse conditions, and the main point in view was to test the time between the entrance of air into the blood-vessels and the occurrence of symptoms therefrom.

EXPERIMENT I. Dog weighing about seventy-five pounds. Ether was given while the vein was being secured and then removed. A large canula was introduced into the external jugular. Blood clotted in the canula, and but little air entered. An unknown amount of air was then blown into the canula, and the dog expired instantly. After a few moments the chest was opened; the auricles were still pulsating, the left slowly, the right 70 times per minute. Heart distended, right side more than the left. Air was present in both sides of the heart, more marked in the right side.

EXPERIMENT II. A small amount of air was injected into the external jugular of a dog, producing labored breathing, a tumultuous action of the heart, and giving a slight churning or gurgling sound on listening over the heart. A larger amount of air was then forced into the vein, causing the arrest of any perceptible action of the heart after a brief space of time. Frothy blood came from the distal end of the jugular, and air was found in the femoral vein and cellular tissue of the thigh. The right side of the heart was distended, and contained air and considerable frothy blood. Some air and frothy blood were found in the left side of the heart.

EXPERIMENT III. Dog, partial chloroform anesthesia. Tried to get air to enter an opening in the external jugular spontaneously; a small amount thus entered causing embarrassed respiration. Air was then forced in, and death ensued at once. The right side of the heart was distended, containing air with a little blood. The left side contained some air but more blood.

EXPERIMENT IV. Dog, partial chloroform anesthesia. Air was blown into the external jugular. Death in two minutes. Right side of heart distended with air and a little blood. Left side contained blood and a little air. Frothy blood came from a cut in the femoral.

The three following experiments were performed under more favorable surroundings than the preceding, and more accurate results were obtained.

EXPERIMENT V. Dog, estimated weight seventy-five pounds. During one minute 60 c. c. of air were injected into the external jugular. The dog struggled considerably and the heart beat violently; slight churning sound heard over the heart. In the third minute 20 c. c. more of air were injected; the churning sound became more marked; the dog stopped struggling and breathed rapidly. In the fifth minute 20 c. c. of air were introduced; in the sixth minute 20 c. c. The dog was then struggling as if for more breath. During the next six minutes 200 c. c. of air were introduced. Immediately after each fresh injection the dog would struggle and whine as if in distress. From this time to the thirty-first minute 560 c. c. of air were introduced. The heart was now very irregular and feeble. From the thirty-first to the thirty-fourth minute 400 c. c. of air were injected. The dog was then convulsed, his eyelids twitched and his reflexes were wholly abolished, and death took place in a convulsion. The urine and feces were extruded.

Thus, altogether over a litre of air was introduced before death took place, showing that if air is introduced slowly the circulation will take care of a large amount of it, though when symptoms are produced they come on immediately after the introduction of the air.

EXPERIMENT VI. In this dog it was proposed to produce death by injecting a fatal amount of air at once. The dog weighed about thirty pounds, and 80 c. c. of air were introduced at once. The dog struggled slightly, and then lay motionless excepting for slight aimless movements of the head. Breathing ceased in eight minutes. At the end of ten minutes the heart was pulsating feebly, 64 times a minute. Cavity of chest opened at the end of twelve minutes. The ventricles ceased contracting at the end of thirteen minutes. The right side of the heart was much distended, and was punctured *in situ*. Much air and frothy blood escaped, and the heart again began pulsating. Frothy blood again collected somewhat in the right side of the heart, and on being let out the heart took a fresh start. Nine minutes from the time of the puncture the heart was contracting regularly 46 times per minute, and did not wholly stop beating until nineteen minutes from the puncture of the ventricles. As the chest cavity was opened, of course, breathing could not start up again. But Professor Senn has shown that by aspirating the heart after the animal has had a fatal amount of air introduced into its veins life may be saved. The lungs in all of these cases were collapsed.

EXPERIMENT VII. In this case it was proposed to endeavor to cause the death of the animal by the spontaneous entry of air into the veins. A dog weighing about forty pounds was used; and, as in all of the other cases, an opening was made into the external jugular vein. The animal was then so held that the head and fore part of the body were higher than the other parts, and the opening into the vein was kept patent. Air entered with a gurgling sound. The dog breathed heavily, whined and struggled, and more air entered as he struggled. He soon became quiet, and in seven minutes was thought to be dying, and was placed in a horizontal position. The heart was beating but feebly. In a few moments he began to show signs of returning vitality, and at the expiration of five minutes was again breathing with fair regularity. The head was again elevated, the vein held open, and air entered as before. In five minutes he was again thought to be dying, and was again placed in a horizontal position, but on showing signs of returning consciousness was for the third time elevated; air again entered, and this time he died—thirty-two minutes from the time the first air entered.

These experiments show that if a small, or even quite a large amount, of air be introduced, or spontaneously enter, into the blood-vessels slowly, the circulation may take care of it, and primarily it may not cause death, but whatever symptoms are produced are produced at once. When a large amount is introduced the result is rapidly fatal. The point upon which special emphasis should be laid is the fact that the primary symptoms cannot be delayed after the air enters. Secondary effects, such as pneumonia from pulmonary embolism may come on later; but not so with the collapse, difficulty in breathing or convulsions, which have been observed in all cases where the air has entered through the uterine sinuses.

In the preparation of this paper much assistance was given by Dr. W. H. Palmer and Prof. H. C. Bumpus, of Brown University, as to them I am indebted for the hitherto unpublished cases and the success of the experiments.

Clinical Department.

A CASE OF SPIRAL FRACTURE OF THE TIBIA.

DIAGNOSIS BY THE X-RAYS.

BY CHARLES E. TAFT, M.D., HARTFORD, CONN.

FRACTURES of the tibia in the lower third of the bone are usually oblique, extending downward and inward, and, in most instances, are produced by indirect violence.

True spiral fractures of this portion of the bone have been considered rare, and, while oblique as to their general direction, have probably been regarded as straight by the attending surgeons. That such a fracture occurs much more frequently than we have realized is undoubtedly true; but it must be evident, that, except in rare instances, it has been impossible of recognition during life by any means of diagnosis previous to the advent of the x-rays.

In view of these facts, it has seemed desirable to me to report the following case of spiral fracture of the tibia.

On October 30, 1896, I was called by Dr. Alcott, of West Hartford, Conn., to attend a boy ten years of age, who had broken his leg while playing football. The little fellow had been playing centre rush, and while standing with his right foot firmly braced in front of him was suddenly twisted sideways by the opposing player and thrown to the ground. He at once felt great pain in the leg and was unable to rise. Dr. Alcott was immediately called, and, after a careful examination, thought he recognized a fracture of both bones of the right lower leg, that of the fibula being a little higher than the break in the tibia.

He applied a temporary splint and dressing, and brought the boy into Hartford, where I saw him in consultation. Chloroform was then administered and a thorough examination made. While it seemed probable that a fracture of both bones existed, we were only able to detect what seemed to be an oblique fracture of the tibia. At this examination no particu-

strate the fracture with an Edison fluoscope; but this was an absolute failure, although we had a powerful, even light and every facility for using it. The reason seemed to be our inability to get the screen sufficiently near the bones, the swelling of the soft parts, the cotton and splints making the intervening

FIG. I.

lar deformity was apparent, a slight depression in the line of the tibia with localized pain on pressure and motion being the only signs of fracture. No crepitus was detected. The limb was placed in a normal position and a felt splint lined with cotton applied.

On November 2d, Mr. Henry Green, of Hartford, brought his portable x-ray apparatus, including the Green-Bauer Crookes tube with auxiliary bulb, to the patient's house, and the negatives of the accompanying wood-cuts were then taken. The development of these negatives revealed a spiral fracture of the tibia. In Figure 1 the plate was placed directly beneath the leg to get the posterior aspect of the bones. Plate 2 was placed on the inner side of the leg. In each case the exposure was twenty minutes, the Crookes tube being placed about four inches from the bones. No splints or dressings were removed.

It is of interest here to note the fact that before exposing the plates an attempt was made to demon-

FIG. II.

strate the fracture with an Edison fluoscope; but this was an absolute failure, although we had a powerful, even light and every facility for using it. The reason seemed to be our inability to get the screen sufficiently near the bones, the swelling of the soft parts, the cotton and splints making the intervening

space so great that the shadow was very indistinct. While the outlines of the bones could be easily seen, there was nothing in the view to indicate a fracture. An additional reason was probably the close apposition of the bones and, in consequence, a rather fine line denoting the fracture.

In view of my experience in this case it would seem inadvisable under similar conditions to depend on the fluoscope alone for a diagnosis, when it yielded a negative or indistinct picture.

The accompanying radiographs beautifully illustrate a long spiral fracture of the tibia. They also show plainly the junction of the epiphysis with the shafts of the bones.

It seems probable that the reason why the fracture involved the tibia alone was because the force was applied but for an instant, and the fibula being the lighter bone, its greater elasticity allowed it to spring back into place almost instantly.

FOUR CASES OF PREGNANCY COMPLICATED BY HEART DISEASE.

BY GEORGE G. SEARS, M.D.,
Assistant Visiting Physician, Boston City Hospital.

THE following cases, which have recently come under observation, are briefly reported as a contribution to the statistics of the cardiac complications of pregnancy. They illustrate the successful issue, which is to be expected in a majority of instances, as well as a number of the accidents which may occur, while the one fatal case adds another to the long series of deaths from this cause, which might have been prevented by promptly terminating pregnancy as soon as it became evident that the usual therapeutic measures were insufficient to check the failing cardiac compensation. Unfortunately, here the patient did not seek advice until the opportunity had passed.

CASE I. Mrs. T., thirty-one years old, a primipara, had her last catamenial period in July, 1895. Her previous history is not noteworthy. At her first visit in October examination showed that the temporal arteries were abnormally tortuous and that the radials were somewhat thickened so that they could be distinctly felt.

The area of cardiac dulness was perhaps a little increased but no murmurs were detected. The pulse was regular, but of only moderate strength. The urine contained no albumin till near the end of the pregnancy when a very slight trace appeared. In January, 1896, she began to complain of dyspnea and had a slight cough, raising on one or two days a little blood-tinged expectoration. These symptoms passed off under treatment and during the last few weeks of her pregnancy she suffered no more discomfort than was natural to her condition. Her feet were slightly edematous. Labor came on at term and was not severe. There were no notable symptoms up to the time when the os was fully dilated and the head had begun to descend through the pelvic strait, then the pulse, which had remained good throughout, suddenly became irregular and intermittent. Ether, of which only a little was required, was immediately given and the child extracted by forceps as rapidly as possible.

After the birth of the child the mother was in a state of extreme collapse; respirations were so shallow as to be barely perceptible and the pulse could not be felt at the wrist. Under hypodermic stimulation, however, she revived, but the re-establishment of the circulation started up a brisk uterine hemorrhage in which she lost an alarming amount of blood. This was checked after the uterus was packed with iodoform gauze by Dr. Chute, to whom I am indebted for the most timely assistance. Convalescence was slow but uninterrupted and mother and child are now doing well. A later examination of the heart showed an accentuated and reduplicated pulmonic second sound. It seems probable that some mitral obstruction exists.

CASE II. Mrs. K., a primipara, forty years old. Except for a serious attack of faintness and dyspnea after climbing up one of the White Mountains twelve years ago she had never had any symptoms which should lead to the suspicion of any cardiac trouble. Her last period occurred in December, 1895, and during the next four months she never felt better in her life. Then she began to complain of dyspnea and of a short, hacking cough, and noticed that her feet were

beginning to swell, but thought little of it as her friends told her that such symptoms were incidental to her condition. They steadily increased, however, and in the latter part of June had become so serious that she consulted Dr. George Haven, who a few days later kindly asked me to see her with him. At that time dyspnea was so great that she was unable to lie down and spent most of the time sitting up in a chair. Her face was dusky, her hands markedly cyanotic, the veins standing out in prominent relief. The legs were greatly swollen, the edema extending nearly to the hips. The area of cardiac dulness was laterally enlarged and over the apex, which was situated in the fifth interspace about an inch outside the nipple line, a very rough presystolic murmur was heard. Over the bases of both lungs there was marked dulness with deficient respiration and numerous medium and fine moist râles. The pulse was 90, regular, but small and weak. The urine was scanty, of high specific gravity and contained a very small trace of albumin. The time for interference had passed and her only chance lay in the possibility that the heart still possessed some recuperative power and would respond to stimulation. During the next two weeks she apparently improved somewhat, and seemed much more comfortable, the dyspnea grew less and the urine increased from about seventeen ounces to nearly thirty in the twenty-four hours, but the improvement could not be maintained and at the end the heart suddenly gave out, death occurring just before the completion of the seventh month.

CASE III. Mrs. C., vii-para, thirty-eight years old, was also seen with Dr. Haven, whose patient she was at the Lying-in Hospital, and I am indebted to him for the privilege of reporting it. During the past twenty years she has had four or five attacks of rheumatism, the last and most severe one being a year ago. Following the birth of her last child, two and a half years ago, she had an attack of very severe precordial pain and dyspnea which lasted several hours, but apart from this she gave no history of anything abnormal in any of her pregnancies or labors. When six months along in her present pregnancy she began to cough, but noticed no other symptoms until the end of the eighth month when she began to grow very short of breath, the cough increased and her feet became swollen. When admitted in labor to the hospital, dyspnea was so great that she could not lie down and had to be delivered sitting up in bed. The first stage lasted eight hours, but the pains were neither severe nor frequent. The second stage lasted six minutes. After delivery there was a sudden attack of dyspnea with cough accompanied by much frothy expectoration. The post-partum loss of blood was considerable. When seen three days after delivery she was propped up in bed, breathing rapidly and somewhat cyanotic. There was marked cardiac enlargement and at the apex both a systolic and a presystolic murmur were distinctly audible, while a double murmur was also heard over the aortic area. Over the third left costal cartilage a very rough to-and-fro murmur was heard either pericardial or pleuro-pericardial in origin, which had disappeared a few days later. There was marked edema at the bases of both lungs. The urine was diminished in amount, had a specific gravity of 1.024, and contained a large amount of albumin. The sediment was composed of much blood with numerous hyaline and fine granular casts. Recovery was gradual, and when

last heard from both mother and child were doing well.

CASE IV. Mrs. C. K., age twenty-eight, was admitted with meningitis to my service in the City Hospital from the Lying-in Hospital where she had been brought a week previously in a convulsion following the birth of twins. Labor had been so easy that no physician had been summoned. No symptoms had ever been present which could be referred to the heart although its area was somewhat enlarged laterally and a distinct presystolic murmur was found just inside the apex beat. Her first child had been born ten months before and was still living.

Beside those patients who have applied for treatment for cardiac disease, whose histories showed that the valvular lesions antedated one or more of their pregnancies, my experience is limited to nine cases where heart disease and pregnancy coexisted. So far as it goes it would show that such a complication, when properly managed is not necessarily a very serious one, if the immediate consequences only are regarded, as but one died (Case III of the present series, with mitral stenosis), and she had already passed the period, when first seen, where help could be afforded in any way. The others, under general treatment or with no treatment at all, were all successfully delivered at or near term, with one exception, also a case of mitral stenosis, when abortion was thought necessary, the patient being still alive two years later. Of these nine cases, four were suffering from mitral regurgitation, three from mitral stenosis, one from a double aortic lesion and one from combined mitral and aortic lesions.

Medical Progress.

RECENT PROGRESS IN LEGAL MEDICINE.

BY F. W. DRAPER, M.D.

DEATH BY ELECTRICITY.

THE cause of death following electric shock is not yet definitely decided. P. A. Fish¹ reports the results of his examination of the bodies of two men after electrocution; in neither was there found any lesion of the nerves or nerve-cells. In summing up the results of his investigations, he says:

"It is not probable that one tissue or system of tissues is selected by the electricity as it traverses the body, although there may be different degrees of susceptibility. Death may be brought about by the killing of the cells in the nerve centres, the electricity in this case, acting as a fixing agent; for as in histology when certain reagents, or in some cases, simply their vapor, are allowed to act on living nervous tissue, this not only kills but fixes or retains the elements of the tissue in the position they held at the time of the action of the reagent."

HYPNOTISM AND CRIME.

In recent years, hypnotism has entered in a number of cases into the defence brought forward by those who were charged with felonious crimes. The first case, however, in which an individual has been tried, convicted and sentenced for the abuse of hypnotic power, was reported by Moritz Ellinger² before the

Medico-Legal Society, of New York. The case was tried in Munich, and the accused (Czynski) was convicted and sentenced under three counts:

1. That he put Baroness Van Z., by means of hypnotism and suggestion in a condition of loss of the will power, in which she, without the power to exert her own will, submitted herself to him in illicit intercourse.

2. That he induced W. by the promise of financial gain, to do things which could only be done by a person properly authorized.

3. That he gave to the brother of the baroness a document which was a false marriage-certificate, for the purpose of securing thereby substantial advantage through the use of the baroness' considerable wealth.

It appeared in evidence that the baroness, a woman of neurasthenic constitution and family predisposition, first went to Czynski, a professional hypnotist, for the treatment of certain supposed diseases. After gradually acquiring the alleged hypnotic power over her and maintaining improper relations with her for several months, he caused her, so it was charged, to marry him, the ceremony being performed by one W., who personated a clergyman and furnished a false certificate. Czynski tried, unsuccessfully, by means of this document to obtain possession of property belonging to the baroness which was held in trust by her brother.

PRIVILEGED COMMUNICATIONS.

The subject of privileged communications was again brought into prominent notice by the well-known case of *Kitson versus Playfair*; ³ and the forcible, if somewhat remarkable, position taken by Mr. Justice Hawkins is worthy of note. He asked Sir John Williams if he "thought it the duty of the physician to inform the public prosecutor if it had been found that the patient whom he was attending had submitted to an unlawful operation." The answer was in the affirmative, that the College of Physicians had so decided. The judge said that such a position would make him very careful in the selection of his medical advisers; and in his charge to the jury, he went further and said that "the theory that it was always the duty of a physician to inform the public prosecutor when he suspected that a crime had been committed, was simply monstrous."

POISONING BY ILLUMINATING GAS.

The numerous cases of fatal poisoning by carbon monoxide in communities where water gas is used as an illuminant, make the following remarks by Dr. John Haldane⁴ of especial interest. Summarizing his observations and experiments which led him to conclude that the "property [residing in carbonic oxide] of excluding oxygen from the blood really affords a complete explanation of its poisonous action, so that this action may be referred solely to oxygen starvation," he adds: "In breathing carbonic oxide experimentally no unusual effects are felt, during rest, until the blood is thirty per cent. saturated; but any exertion causes dizziness, loss of power and shortness of breath. These symptoms, occurring on exertion, are the first symptoms of carbolic-oxide poisoning. With the blood more than thirty per cent. saturated, throbbing of the vessels of the neck, and slight shortness of breath are felt even during rest. As the saturation of

¹ Journal of Nervous and Mental Diseases, January, 1896.

³ Gaillard's Medical Journal, April, 1896.

⁴ British Medical Journal, October 3, 1896.

the blood increases, the power of movement becomes more and more impaired and the senses are also affected. At fifty-per-cent. saturation, I found it scarcely possible to stand, but otherwise there was no positive discomfort."

The author also reports observations made upon one hundred and twenty men killed in three great colliery explosions, in which death was due to poisoning by carbonic oxide. He divides the victims of these disasters into three groups: (1) Those who had apparently died slowly in air containing a small percentage of carbonic oxide. (2) Those who had apparently died more quickly in air containing a larger ratio of carbon monoxide. (3) Those who had died in fresh air from the after-effects of carbonic-oxide poisoning.

The first class was much the largest, and the bodies presented "an extraordinarily life-like appearance," the pink color of the skin and mucous membranes being very striking. The venous blood in several instances was found to contain from 79 to 83 per cent. of carbonic-oxide saturation.

The second class was much smaller, the color effects were less characteristic, and the venous blood was found to contain 63 per cent. of saturation.

In the third class, which included those who died after being brought out alive, the appearance of the bodies, and the amount of carbonic oxide in the venous blood varied within wide limits, and this variation is explained by the time during life in which the poisonous gas had the chance to escape from the blood. From experiments upon himself, the writer found that "it would probably require about six hours for the blood of a man nearly poisoned by carbonic oxide to completely free itself from the gas."

POISONING BY OXALIC ACID.

W. Hall White⁶ reports two cases of acute nephritis resulting from oxalic acid poisoning, one of which ended fatally in six days after the ingestion of the poison. The symptoms were scanty urine and albuminuria; the fatal case had almost complete suppression. In neither case was there edema, high-tension pulse, or hematuria. In both cases, the urine contained granular and epithelial casts, together with calcium oxalate crystals. The first specimen of urine passed after taking the poison contained albumin and crystals. In the case which recovered, the crystals disappeared from the urine in twenty-four hours; the albuminuria persisted four days; and the casts were observed for a week in the specimens examined. In the fatal case, the albumin and crystals remained in the urine until the end. The post-mortem examination in this case showed acute tubal nephritis, and a very considerable number of oxalic-acid crystals were found in the kidneys.

FOREIGN MEDICAL MEN IN ITALY.—Among the governments which have taken measures to prevent the practice of alien medical men therein, Italy must now be numbered. Formerly a foreign qualified medical man was permitted to practise among the foreign population, as well as among the natives, provided that he paid the license fees and taxes. It will now be necessary for foreign practitioners to obtain a diploma from one of the Italian universities.

Reports of Societies.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

PAUL THORNDIKE, M.D., SECRETARY.

REGULAR Meeting, Wednesday, December 2, 1896, DR. H. L. BURRELL in the chair.

DR. H. A. LOTHROP read a paper on

HERNIA EPIGASTRICA, WITH A REPORT OF CASES.¹

DR. CUTLER: In the first place I want to congratulate Dr. Lothrop on the very successful manner in which he has worked up his subject. It is certainly quite an important one, and one which has received relatively little attention. I have looked over my cases, and have found that I have had quite a number of umbilical and two of epigastric hernia, and I am sorry to say none of them have been operated upon. There were two I thought I had got to the sticking-point of an operation, but one of them finally refused and the other has gone into other hands.

As far as the frequency of epigastric hernia is concerned, I have not any figures of my own; but in one of the German clinics (Bonn), a general ambulatory one, I think the percentage was something like one per cent. in 3,420 cases—something like 33 persons, which makes a little over one per cent. Witzel, I believe, found something more in his collection of cases, but I have forgotten the locality of his clinic.

As far as the location is concerned, it seems to me that some of the cases of so-called umbilical hernia are quite this same thing. The hernia is found just away from the umbilicus, which latter can be felt distinctly at one side, and the symptoms are identical, so that if I were to give the limits of epigastric hernia I should have its lower boundary at the umbilicus, and I should say that some of the cases of epigastric hernia are as low as the umbilicus; in the cases I have seen, with one exception, most of them have been nearer to the umbilicus than to the ensiform cartilage.

Dr. Lothrop's explanation of the pathology is a beautiful demonstration of the subject, and seems to me quite conclusive. It is quite in accord, I should think, with certain dissections I saw figured in Paris. I did not have the chance to examine them carefully because I only had a few moments. In the old Dupuytren collection in Paris there is a dried anterior abdominal wall which shows, I suspect, very much this same thing described by Dr. Lothrop.

As far as the size of these herniæ is concerned, the ones which the medical man sees are relatively small, the size of a bean or a little larger. In all the cases I have observed it has not been possible to entirely reduce the hernia. There has been some little portion of it left after taxis. Concerning the contents of the hernial sac, it is omentum; and I believe it is only the larger ones that contain any organ like the stomach or intestine. If the rupture were down near the umbilicus, of course, except in a greatly displaced stomach, you would not find hernia of the stomach; it is only in the larger ones that you get anything else than omentum.

To make the hernia come out more, cough and straining, as Dr. Lothrop has said, is sufficient to do that, but I have made it appear a little more prominently, I think, when the patient is lying down, by

⁶ Journal of Pathology and Bacteriology, July, 1896.

¹ See page 175 of the Journal.

placing him on the side and having him bend over. I demonstrated that a few days ago in a patient at the hospital. I turned him over on his side and had him bend forward, and his rupture came out as a great mass. This I have been able to do in the few cases I have seen almost always.

As far as the etiology is concerned, the cases which have been mentioned are very interesting. In those I have seen vomiting has been spoken of in connection with the etiology, but I think it is hardly likely to have been the cause. It probably is something else in addition. Then trauma and cough are spoken of. Certainly cough cannot be an effective etiological factor in many cases, because we see numerous cases in medical clinics where cough is a very pronounced thing, especially whooping-cough, and we do not see anything like epigastric hernia occur. The disease must be extremely rare in children. All the cases I saw were at least forty years of age. I have never seen it in females.

As far as the symptoms are concerned in the cases I have seen there has been almost invariably tenderness on pressure. It may not have been very severe; in one or two only when you pressed quite vigorously could you get a sensitive place in the rupture, and quick pressure or harder pressure in other parts of the abdomen would give rise to no pain. The omentum has always been adherent in the cases I have seen, and pain has occurred, usually referred to the epigastrium; and especially has it occurred after bending back or stooping. Why stooping should give rise to it I do not know. In one case the man felt perfectly well until he had eaten a big dinner and straightened up and the pain came on instantly. Another curious thing is this pain spoken of as coming on usually an hour after a full meal. That is understood in this way: when you consider the stomach, its function is double—that of motion, the essential one, and secretion, which is not so essential. If anything disturbs the motion of the contents of the stomach, you are going to have pain for the reason that there is allowed to undergo in the stomach, from stasis of the contents, a fermentation which gives rise to pain and secondary disturbance. A very curious thing sometimes observed in these cases is increase in the amount of gastric juice secreted and increase in the acidity; and those are the symptoms Dr. Lothrop has spoken of. The pain is probably due to arrest of gastric peristalsis and of the onward passing of the food from the stomach into the intestine and secondary decomposition, and in some way not yet understood some disturbance of the secretion, perhaps through some nervous influence. The neurasthenic symptoms are the hardest to combat and they occur usually towards the end of the case, after a person has had a good deal of treatment and many things said to him.

As far as the differentiation of these tumors is concerned, of course, I take it the fatty tumor is about the only thing you have to fear of confounding. I have seen a case where I could not determine whether it was simply fat, or whether there was a collection of omentum in a hernia.

I saw in Ewald's clinic this year a person who had severe symptoms from epigastric hernia occurring in the second position Dr. Lothrop has drawn upon the board. He had not only one there, but one on the left considerably smaller; and then he had on the back outside the sacrum another hernia, and that gave

rise to the same symptoms. I think the patient was a man. He had been under treatment some time, and nothing had helped him. He refused operation.

So far as the prognosis after radical operation is concerned, that depends upon the rapidity with which the symptoms have followed the occurrence of hernia. In the older cases that have lasted for years so many secondary complications have come up that an operation would have to be followed by a prolonged set of medical procedures before you could expect to do very much good.

The treatment, it seems to me, is almost exclusively surgical.

I have a case under observation, that came the 5th of last month, with symptoms of about a year's duration. The diagnosis was omental hernia near the umbilicus. Each time a crisis came on the patient was feeling perfectly well. His bowels would be constipated immediately before or about that time, and they were usually not so. The attacks always began with pain near the umbilicus, soon followed by vomiting; and nothing was retained. The abdomen was particularly tender at and near the hernia. As far as the digestion was concerned, the gastric juice did not show much of anything. I found in putting him in the various positions, I could get out a knuckle of omentum about as large as the end of the thumb; and although the slit was transverse and not round, I had him put on, as he did not consent to operation, a piece of metal and bound it on tight. That was the 10th of November. There has been no material improvement.

I saw at the hospital, two months ago, a person who had a cancer of the stomach; and it is rather common to have these herniæ occur in cases of that kind. I think Boland found eight or ten among his 40 cases. This man had suffered some little time with disturbance of his digestion, and his symptoms connected with his hernia had only been of recent origin. There was localized pain not relieved by hot drinks, and he would get easy frequently by stooping over; that was, of course, the pain due to the hernia and not to the cancer. It was a little to the left of the median line and half-way to the umbilicus. I never understood before why these herniæ appear a little to the one side or the other of the median line, but Dr. Lothrop has explained it satisfactorily. In the two cases I have seen the hernia could not all be reduced, and I do not know in what proportion of them it can be. There is no single symptom or set of symptoms connected with the stomach but what may come with this disease. I do not know about vomiting of blood; but changes in the amount of secretion, changes in the character of secretion, and changes in the acidity have been observed in these cases.

As far as the icterus is concerned, that has sometimes been found to follow slight adhesions of the liver or parts of the ducts or gall-bladder either to the abdominal wall or to some of the adjoining viscera. I have seen one case where an operation was performed by Dr. M. H. Richardson for a possible gall-stone, and merely a slight adhesion was found of the gall-bladder to the upper part of the liver by means of a cicatricial band. That having been divided, the person who had suffered from fever for several months was entirely relieved, and the jaundice which had existed some little time disappeared, and the patient got along very well. She has since continued to have hypochondriacal symptoms, but those she had a good many years

before. The operation succeeded in doing what it set out to do, namely, to relieve the patient of her jaundice and her fever. We expected to find a gall-stone, but did not find one. I saw at the clinic of Rosenheim, in Berlin, the same thing this year.

DR. RICHARDSON: I think Dr. Lothrop has given us a very instructive and interesting description of this form of hernia. I dare say, when attention is called to this subject, we shall find the cases much more frequent. I have noticed often, in cutting through the epigastrium, that in going through the posterior rectal sheath the fat protrudes in the form of a hernia. I think the etiology given by Dr. Lothrop is interesting. I have seen several cases of epigastric hernia, but the only one I recall anything about is the one Dr. Lothrop has quoted. The hernia is precisely like the umbilical hernia, when large. The opening in the aponeurosis is smooth, sharp, precisely like umbilical hernia. The omentum is adherent to the sac and there are partitions as in umbilical hernia. I think we ought to bear in mind the possibility of these forms of hernia in operating upon what seem to be fatty tumors in this region, and also to avoid incisions in cold abscesses, which are not infrequent near the margin of the ribs. There is very little to say except in commendation of this paper. My experience is so limited I do not feel at liberty to say more.

DR. ELLIOT: I am surprised to hear that these herniæ are so rare. I can only remember operating on this, the one case which Dr. Lothrop has reported, and one or two of the little cracks he speaks of. I have had no special experience. I think part of the pain in the stomach spoken of by Dr. Cutler, is probably due to adhesions, because almost all these herniæ have adhesions to the abdominal wall. I believe that in doing these operations one should not only cut out all the adhesions and the tissues attached, but the peritoneum should be cut away from the wound, and in stitching up the peritoneum should not be included. The peritoneum when included, makes a tendency to a pocket, which gives a chance to recur. The cicatricial tissue with no peritoneum in it is stronger and better than cicatricial tissue with the peritoneum turned in.

DR. A. T. CABOT mentioned a case illustrating the importance of investigating the gall-bladder in these patients when there had been any jaundice. This patient, operated upon last February, had a hernia at the umbilicus; and operating for its radical cure, in view of past attacks of jaundice which she had had, he examined the gall-bladder and found it full of gall-stones. After closing the hernial ring, he made an opening over the gall-bladder and removed a great number of calculi. The woman made a good recovery.

DR. GREENE: I was very much interested in Dr. Lothrop's cases. I have seen, I think, some 15 or 20 cases of this form of hernia; and if we should widen the region to the extent Dr. Cutler spoke of, I think more than that. Almost all of these arose from trauma. Three cases in particular happened in railroad accidents, where a collision took place and the person was thrown forward, striking the epigastrium against the corner of the seat in front. One of those cases was a well-known physician of this city, now deceased. In regard to the size of the tumors, I recall one case in particular that was very large. The separation of the linea alba was at least three or four inches in length, and a very large tumor was formed

in that case. These cases, as a rule, can be treated in a palliative manner quite readily by a pad and band around the body; but if they can be cured as readily by operation as the cases reported, that will certainly be a great advance upon the other method of treatment. I was rather surprised to hear that the gastric disturbance was so great in these cases. In the cases I have seen there was but little complaint made of that symptom.

DR. BURRELL: I remember that in one instance some time ago, I operated on what I supposed was an umbilical hernia. In making an incision down upon the neck of the hernia, I found precisely what Dr. Richardson has spoken of, a ring surrounding the neck of the sac, with the fibres concentrically arranged, interlacing in the fashion of which Dr. Lothrop speaks. It was only when I had exposed the hernia that I recognized that it was not umbilical, but it was what I called ventral. I reduced the hernia, closed up the ring in the abdominal wall, thought it rather odd that a ventral should simulate an umbilical hernia; and it is only since hearing this admirable paper of Dr. Lothrop's that I have clearly recognized this class of case.

DR. J. W. ELLIOT reported a

CASE OF RETROPERITONEAL EXTIRPATION OF A KIDNEY, WITH ITS URETER.²

DR. WOOD: I have very few words to say, and, of course, only from the urinary point of view. The great importance in this case, and in many others, of the examination of the urine before the operation is, of course, to determine the condition of the other kidney and in this case the examination I made April 13th showed that the well kidney was secreting 900 c. c. of urine, which is a very fair amount for a woman in that condition, and that the percentage of urea was 2.5 per cent., showing that this kidney was doing fully its normal work, although it was apparently a little lame and the sediment contained here and there a small cast. It occurred to me at the time that a possible explanation of that was that it was more or less congested and was really doing the work of the other kidney, so that it was natural to expect that it would be somewhat hyperemic. The kidney which was removed was doing scarcely any work; it was nearly destroyed by pyonephrosis, the secreting structure only being able to eliminate less than one per cent. of urea, and that with a small amount of fluid. The cases which have been followed out have shown pretty conclusively that the other kidney compensates completely for the loss of its mate, that it becomes hyperemic for a time, and that the congestion finally disappears; in this case on May 12th, less than a month after the operation, I was only able to find one cylindrical body, the origin of which was very doubtful whether it came from a renal tubule or, there being a little leucorrhœa, whether it was from some vaginal duct. In another case of the kind, in which I was able to follow up the urine to the complete disappearance of the casts and the complete subsidence of the renal congestion, one which Dr. Scudder reported where a nephrectomy was done for cystic adenoma, the casts disappeared in about four months from the time of operation. In another case of Dr. Elliot's I had an opportunity to examine the urine three months after the operation; there was then, although it was getting along nicely,

² See page 173 of the Journal.

an occasional cast found at the last examination I made, the remaining kidney secreting 21 grammes of urea. The patient is all right at the present time, and undoubtedly the congestion finally disappeared.

In deciding as to an operation, the condition of the other kidney is important, and that is determined by the facts just mentioned, namely, the quantity of urine secreted by this kidney and the percentage of urea which that urine contained. If it is normal, or more than normal, it is pretty sure that the kidney will be able to take care of the work thrown upon it by the removal of the diseased kidney.

DR. A. T. CABOT said that it made the case a very interesting one, in that the examinations of the urine were so carefully made, enabling us to exactly follow the condition of each kidney. He was inclined to think the improvement in the amount of urea which followed the operation was largely to be accounted for by the fact that before operation the patient was emaciated and taking but little food; whereas, later, when she was convalescent and taking more food, the eliminated urea naturally increased. Furthermore, it seems probable that the competent kidney was brought to this increased degree of efficiency by a gradual process, the other kidney being slowly destroyed by disease; therefore there was less danger of overcoming this power for excretion by throwing extra work upon it than there would have been in the case of a perfectly healthy kidney where the other was destroyed by a gun-shot wound or otherwise.

It was a great advantage in this case that the exact amount of work of each kidney could be estimated before the operation. This adds an argument in favor of doing a nephrotomy first in case of doubt or in cases where the patient seems at first unable to stand the severer operation of nephrectomy. He was inclined to feel that even a laparotomy, enabling the operator to examine both kidneys before operation, does not give a really adequate idea of the amount of work that each one is doing. This could be better discovered by catheterization of the ureters in cases of doubt.

In regard to the incision, he liked that employed by Dr. Elliot better than one more on the abdominal surface for the extirpation of an organ so disorganized and filled with pus as this was.

It was particularly proper in the reported case, where the capacity of the other kidney was known and intra-abdominal examination therefore unnecessary. He had pointed out in a paper read in 1891 the advantage that this incision has in enabling one to follow the ureter far down in the pelvis. He was interested in Dr. Elliot's experience in this respect, because, although he had demonstrated the point to his satisfaction on the cadaver, he had not had occasion to deal with the ureter far down in the pelvis through this incision in the living. The fact that Dr. Elliot could get his stitches into the canal at all satisfactorily shows how accessible that portion of the canal was made by this incision.

In regard to the treatment of the stump, he liked Dr. Elliot's method of closing it off. In case the whole canal was suppurating and in a foul condition, one would be warranted in spending the extra time necessary for bringing the end down into the vagina in the manner carried out by Dr. Kelly.

DR. RICHARDSON: I feel a very great interest in this subject, and especially in the two points Dr. Elliot has made. The first point is with reference to

the treatment of the ureter after removal of the kidney. I have seen in 20 nephrrectomies, of which I can recall only 16 at this moment, no trouble at all after cutting the ureter and leaving it. Some of these cases have been fatal, but the fatalities have been immediate, with one exception; and the greatest mortality has been in those cases in which the whole work of urinary secretion has suddenly been thrown on the remaining kidney, for example, in traumatism and in cases of malignant tumor, in which there is a large amount of secreting substance left undoubtedly.

I have brought a drawing which illustrates a case of tubercular pyonephrosis in which the ureter on the left side was diseased as far as I could reach. I think this is very similar to Dr. Elliot's case. I first removed tubercular tubes and ovaries; then I removed the kidney. She recovered from the operation, but died later from tuberculosis of the lungs. This is a picture of the kidney with a contracted ureter. The second shows a section of the same kidney, and I would like to show that with reference to the second point Dr. Elliot raised. It does not seem to me necessary to look after the ureter unless that is distinctly diseased. The second point brings up the question of nephrotomy and nephrrectomy in cases of pyonephrosis, whether the latter is not better for various reasons, and among others that the remaining kidney does better work untroubled by the remnants of a diseased kidney. I have felt in many cases that there is no use at all saving a kidney like this one and the one I am passing round. Here is a kidney I removed yesterday, a case of pyonephrosis, in which I thought of doing an operation, which consists in converting a number of small cysts containing pus into one large one, and in overcoming the obstruction which causes the condition. Here is the pelvis of this kidney, and there was no escape of pus at the operation. As far as my experience goes, these kidneys are all very foul; the pus is very disagreeable; and it always has seemed to me, until talking with Fenger, that it was folly to try to save such a kidney. There may be cases in which it would have been wise if it were not a tuberculous kidney, to save this secreting substance; but my feeling is that in cases of this kind in which patients have suffered many months from the chronic poisoning of such an offensive mass as that, reduced excessively in weight, and life a burden, it is much better to remove the kidney entirely if it is diseased as this is. If by nephrotomy we can preserve the kidney, it is perhaps a wise thing to do; but the results, as I have seen them, have been so encouraging in the removal of kidneys of this kind that I am inclined not to subject the patient to the risk of prolonged drainage; not that those risks are very great, but, as Fenger has reported, it takes three, four or more operations. My opinion is that, first, in the majority of cases it is not necessary to bother yourself about the ureter; and, in the second place, in cases of complete disorganization of this kind, it seems to me not the best thing to try to save, but to remove the kidney immediately.

With regard to the incision, I feel that the operation should be done in the right flank; and, in the question of incision, it seems to me there should be but one principle, an incision which will allow one to tie the vessels without trouble, and that can be done by the lateral incision; and, secondly, to follow the ureter that incision need never be carried long in either direction. I do feel very strongly the importance of open-

ing the peritoneum and determining the condition of the kidney on the other side. I do not think it adds to the danger. I have seen the removal of a kidney in which there was a quart or more of this pus which flowed into the peritoneal cavity, but not the slightest trouble from it. I have never seen a case of death from peritonitis after the removal of these kidneys with the peritoneal cavity open. I think the results show there is little or no danger of peritonitis.

DR. REYNOLDS: I came not intending to speak, and cannot give figures as accurately as I should like, but I have had some experience on one of Dr. Elliot's points. I have catheterized the ureters in quite a large number of cases, both in cases of comparative health, and in cases of pyonephrosis, and have had most of my urines studied with care, owing to the kindness of Dr. Ogden. I feel very sure that the introduction of the ureteral catheter has some effect in lessening the amount of urea which is secreted during the time it is in the ureter; but I feel very confident that its use enables us to estimate the relative importance of the two kidneys with considerable accuracy, and I have never any diminution after its use. As regards the information that can be occasionally derived from such careful study of the urine before operating, I should like to relate briefly a case in which the ureteral catheter has so far saved me from operating, and certainly saved me from a very serious mistake. A patient was sent me not long ago with the diagnosis of a probable pyonephrosis. She had been ill twenty years, dating her disabilities from an illness at that time called typhoid fever, but which may well have been the onset of the suppuration. She was complaining of frequent, more or less painful micturition, and of residual urine which had to be drawn by catheter. Asking her whether there was anything else the matter, she acknowledged a pain in the right side far up under the ribs, and in the right groin. I examined her vaginally, and found the right ureter thickened and tender. I introduced a vesical catheter, after she emptied the bladder, and drew off six ounces of about the foulest fluid I ever met with. That was examined by Dr. Ogden, who reported that it contained a fair percentage of urea. I made the provisional diagnosis of a right-sided pyonephrosis. The patient was in a pretty ragged state of health, and was not a good subject for operation. I introduced the ureteral catheters the following day. I obtained from the presumably affected right side, a normal urine containing almost exactly the amount of urea that had been found in the mixed specimen, and from the left and presumably normal side nothing but foul disorganized pus with the merest trace of urea. Had I been forced to operate on that case without the ureteral catheter, I should have opened the sound kidney and killed the woman, the other kidney secreting about .2 % (0.002) of urea. As I shall probably report the case in detail, I shall only add now, that the patient improved greatly after ureteral drainage, that the thickened right ureter, the right-sided pain, and a tuberculous family history made me doubtful of the condition of the right kidney, and that I have therefore as yet avoided operating upon the left side.

DR. BURRAGE: I would like to mention a case I operated on two years ago, where I made the diagnosis with ureteral catheters. The case had been under treatment five years in Nova Scotia, and had a tubercular cystitis. I diagnosed tubercular pyelitis of one

side, and afterwards removed the kidney. Dr. Ogden, of the Harvard Medical School, kindly made a quantitative estimation of the urea in the urine from each kidney. I have heard from the patient recently, and she still suffers with cystitis more or less, but made a good recovery from the operation. As regards the ureter which was enlarged, I simply tied it off and left it. I afterwards, in examining and treating the bladder for tubercular cystitis through the Kelly cystoscope, saw pus coming from the ureteral orifice on that side, so that it seemed to me in this case, the cystitis was kept up by pus which came from the diseased ureter which had been left long, and that the patient would have done better had the whole ureter been taken out.

DR. ELLIOT: I recognize the value of ureteral catheterization; and in this case I was urged to do so, but declined. I had agreed to take the kidney out for her condition in life, without any regard to the pathology of the case, and I had made up my mind to do it. I did not care to run any risk of diminishing the amount of urea which was already small. I had first-rate evidence of what was going on in the kidneys. The only doubt I had, was whether all the urine came out of the fistula or only a part, and the ureteral catheter would have been of great value to me, but I did not care to run the risk of having the patient slip through my fingers. I had made up my mind that her condition warranted nephrectomy for social reasons.

As to Dr. Richardson saying after 20 nephrectomies the ureters had been all right, I am quite prepared to agree with that and more too. Disease of the ureter is very rare. Having had this case, I should always look at the end of the ureter before I cut it off, that is all. I did not mean the ureter should be taken out in every case. It is merely suggestive to have had a case where the pyonephritis was in the ureter itself.

DR. CABOT thinks I made rather a strong point of the increase in the urea after the kidney was removed. I tried to explain this increase in the way Dr. Cabot does. It was my first impression that it was due simply to an improvement in her general health. But what made me think that is not a true explanation, was this: before the operation this patient had increased the amount of urea, under tonics and being sent out of doors, from 180 to 240 grains a day. This was our best showing while she used the diseased kidney. The first week after the operation she had uremia and two or three days of vomiting most of the time, and ate very little, and yet the average amount of urea for the first four days of the second week was quite as much as before the operation; also, in five weeks from that time her general health was probably about the same as just before the operation, but the amount of urea had increased very much. But suppose the general health was better, that would be practically the same point I mean to make: if a piece of a kidney suppurating moderately after a nephrotomy will impair the general health or the amount of urea, or both, for months, it pays to take out that piece of kidney rather than leave it. What the exact explanation is I do not hope to be successful in making, merely that it is quite startling to look at this chart and see how much the urea increased, and it is more startling considering her condition at the time. Whether there is anything in the point of reflex irritation I cannot say, but if it is shown that the general health improves my point is made.

DR. A. T. CABOT showed a specimen from a case of

ADENOMA OF THE SIGMOID FLEXURE,

which was removed by operation. The specimen consisted of a tight annular stricture of dense hardness, less than an inch in width, which, by its contraction had closed the lumen of the gut.

The patient was a young woman of thirty-one who, always of a constipated habit, in the winter of 1895-96 had an attack of stoppage of the bowels which was relieved by medicine. A second attack followed in April, which led to such complete occlusion that an operation had to be done for relief.

An opening was made in the descending colon, and an artificial anus established. At this operation search was made for the cause of obstruction; but, in the enormously distended condition of all the intestines, this was not found. Later, the continuing obstruction in the sigmoid flexure led to the suspicion of malignancy, which was confirmed by the appearance of mucus and, occasionally, of blood in the washings of the rectum.

Examination under ether now revealed the presence of a little, hard, annular stricture in the sigmoid flexure, with a small amount of nodular new growth projecting into the bowel from the inside of the stricture. So close had been the contraction that the lumen of the gut was completely occluded. The abdomen was opened, and this mass cut out with considerable margin of healthy intestine above and below. The disease apparently had not extended deeply into the mesentery, nor were any glands found which indicated a generalization of the growth. The bowel was united by an end-to-end suture, and the patient did well, except that the wound through the abdominal wall suppurated in consequence of the close proximity of the artificial anus.

The microscopical examination of this growth showed it to be an adenoma.

A LARGE ABDOMINAL TUMOR.

DR. MIXTER: Yesterday I took out a large abdominal tumor. As that was not a cyst and this is the same tumor, it is rather remarkable on that account, and also remarkable because it is an uncommon form of abdominal tumor. The patient was a married woman, thirty-one, never pregnant, but had noticed the abdominal enlargement over a year. It did not feel like a fibroid, but more like a multilocular ovarian tumor. On opening the abdomen, I found a mass rather doughy in feeling, and on putting a trocar into it no fluid escaped except a little serum when the trocar was withdrawn. The incision had to be continued up above the umbilicus two-thirds of the way to the ensiform cartilage. I found the ovary attached to the top of it, and on one side was a mass which was evidently uterine fibroids. This tumor would weigh about fifteen pounds. I split the peritoneum and began to shell it out, tied off the broad ligaments, uterine artery, etc., and finally the whole thing was shelled out. The lower part of the body of the uterus and cervix was tied off; and after stopping the hemorrhage, which was considerable from a great many small points, the peritoneum was finally sewed up, and completely covered in the whole bottom of the pelvis and left no raw surface exposed. This tumor extended down in between the bladder and the uterus, so that the whole posterior surface of the bladder was exposed and I could see the ureters. It oc-

curred to me that this might possibly be a form of tumor of which I had seen one case before, but it seemed so intimately attached to the uterus, it never occurred to me it was not an edematous uterine fibroid.

AN X-RAY PHOTOGRAPH.

DR. BOLLES, through Dr. Burrell, showed an x-ray photograph of a needle which rested on the palmar surface of the fifth metatarsal bone beneath the flexor tendon.

TUMOR OF THE KIDNEY.

DR. WENTWORTH showed a tumor of the left kidney, removed by Dr. Burrell from a female child two and one-half years old. The greater part of the kidney is present on one side of the tumor. The capsule of the kidney is continuous with that of the tumor, and is much thickened over the tumor. The consistency of the tumor is very soft. On section, in one portion there is an area of necrosis, about four centimetres in diameter, which is brownish-red in color. The remaining portion shows areas which are gray and translucent, and others which are more white and opaque. There are numerous cysts of various sizes, up to two centimetres in diameter, which contain clear fluid. The tumor is very vascular. A narrow rim of cortex is all that remains of the kidney. The pelvis is much dilated, and is filled with a papillary growth which extends down into the ureter for a distance of five centimetres; extension into the vessels of the kidney cannot be made out. The weight of the tumor is 770 grammes. The nature of the tumor cannot be made out with certainty from frozen sections: but it is evidently of a malignant and complex nature.

Recent Literature.

System of Surgery. Edited by FREDERIC S. DENNIS, M.D., Professor of the Principles and Practice of Surgery, Bellevue Hospital Medical College, etc., assisted by JOHN S. BILLINGS, M.D., LL.D. Edin. and Harv., D.C.L. Oxon., Deputy Surgeon-General U. S. A. Vol. IV. Tumors, Hernia, Surgery of the Alimentary Canal, Appendicitis, Surgery of the Liver and Biliary Passages, Surgery of the Uterus and of the Ovaries and Tubes, Gynaecological Surgery, Symphysiotomy, Surgery of the Thyroid, Surgical Peculiarities of the Negro, Surgery of the Female Breast, Use of the Röntgen Rays in Surgery. Profusely illustrated. New York and Philadelphia: Lea Brothers & Co. 1896.

In this volume we have the completion of the work. The articles presented are of great interest, and the excellent standard of the previous volumes is fully maintained. The most notable articles in the volume are: "Surgery of the Alimentary Canal from the Pharynx to the Ileo-Cæcal Valve," by Maurice H. Richardson, M.D. and Farrar Cobb, M.D.; "Surgical Treatment of Appendicitis," by Charles McBurney, M.D.; and "Surgery of the Thyroid Gland," by Robert F. Wier, M.D. But we do not wish to imply that the others are not admirable. Dennis's "System of Surgery," as a whole, must be considered one of the most complete systems that has been presented to the profession.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, FEBRUARY 25, 1897.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.**SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.**All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.**All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.**Remittances should be made by money-order, draft or registered letter, payable to*DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.**THE DEVELOPMENT OF ABDOMINAL SURGERY DURING THE LIFETIME OF ONE MAN.**

THE recent death of Sir Spencer Wells, naturally brings up the thought of the growth and progress of abdominal surgery during the lifetime of him who might be called its father. It was the birth of abdominal surgery from ovariectomy, coincidently with the introduction of the antiseptic treatment of wounds by Lister, that has made its progress so rapid and brilliant. The greatest discovery of modern surgery is the discovery of anesthetics; the greatest advancement of modern surgery has been the introduction of aseptic surgery, and particularly of aseptic abdominal surgery. The lifetime of Sir Spencer Wells has witnessed both of these great events.

He saw much surgery, in his youth, in the Leeds Infirmary, and later attended the lectures of Hey and Teale. He afterwards studied in Dublin and in St. Thomas's Hospital in London. Later on he entered the British Navy as an assistant surgeon, served through the Crimean War, and at its close returned to London. He had learned much in regard to the tolerance of the peritoneum, from having seen recoveries after severe injuries from military projectiles, and this knowledge and experience he soon turned to account.

Spencer Wells was the first to note the importance of this remarkable tolerance of the peritoneum. The occasional, in fact frequent, occurrence of stabs in the abdomen, letting out the intestines, in which the patient, covered with dirt, was carried to the hospital, where his bowels were washed clean and replaced in the abdomen, and where he almost invariably recovered, had taught surgeons nothing in regard to the innocuousness of wounds of the peritoneum; on the contrary, such cases were regarded with dread, and their convalescence was looked upon with wonder. Still more severe injuries by stakes and pitchforks penetrating the abdomen only served to cause the in-

struments of these wounds to be preserved in museums and the patients to be exhibited as surgical curiosities. No one saw and acted on the evident truth that a clean, simple, incised wound of the peritoneum, such a wound as we should now call aseptic, was as harmless to the peritoneum as to any other tissue. Spencer Wells saw this; he was an observer; and the wonderful recoveries he had seen after shell-wounds were not exhibited to blind eyes.

His first completed ovariectomy was done in 1858, the pedicle was tied with whip-cord and the ligature was brought out through the wound, and came away on the twelfth day bringing a large slough with it. The patient recovered. During the eight years from 1858 to 1864 Sir Spencer operated one hundred times with thirty-four deaths. This mortality was very large; but Wells was honest, reported all his cases at great length and established the operation on a firm foundation.

After ovariectomists had proved that the abdomen could be freely opened, and that the abdominal organs could stand any necessary handling without injury, other abdominal tumors were successfully removed, the first being fibroids of the uterus. After it had been learned that wounds of the bowel, made during an ovariectomy, united if carefully sewn together, and that the functions of the bowel were restored, then, as a sequence of this discovery, laparotomy was done for the purpose of curing fecal fistulæ and other troubles in which the continuity of the bowel had been obstructed, or obliterated; and these operations soon became almost always successful. Intestinal surgery had its origin in ovariectomy.

Next, gangrenous portions of bowel in umbilical or other herniæ were excised, and the cut ends of the bowels were successfully united. The abdomen was opened on account of gunshot injuries and the perforations of the bowels were sewn up. Various devices were brought forward to unite the disconnected bowel, such as Seun's plates, Abbé's rings, and the very successful invention of Murphy's button. To American surgery the world is indebted for these inventions, as it was to McDowell, of Danville, Ky., for the invention of ovariectomy in 1809.

Soon all sorts of operations began to be done. The spleen was removed; caucers of the stomach and intestine were cut out; perforations of the intestine by bullets were sewn up; gall-stones were removed from the gall-bladder; foreign bodies from the stomach and bowels; calculi from the kidney; cancerous, sarcomatous, cystic and otherwise diseased kidneys were extirpated; divided ureters were sewn together or transplanted into the bladder or intestine; the pain and discomfort from floating kidneys was relieved by sewing these organs in place; tumors of the liver (*mirabile dictu!*) were successfully cut away; supra-vaginal hysterectomy in cases of confinement with deformed pelvis was done; Casareau section became almost always successful; Fallopian tubes distended with pus were discovered and removed; the abdomen was

opened in cases of intestinal obstruction; tubercular peritonitis was cured by simple abdominal incision; pressure forceps for saving time in securing bleeding vessels were invented by an ovariologist; Loreta, of Bologna, cured an aneurism of the mesenteric artery by filling the sac with fine wire. To describe all the advances of abdominal surgery during the lifetime of Spencer Wells would far exceed the limits of this notice.

When Spencer Wells began to practise, the distinction between a surgeon and a physician was that the former dealt with maladies and diseases on the outside of the body and the latter with those of the internal organs, now the organs inside the body are almost as freely handled by the surgeon as they are discussed by the physician. To Spencer Wells it was given in his lifetime to witness all this progress and tremendous advance in abdominal surgery and to realize that all these successes within the abdominal cavity owe their inception and execution to the knowledge gained by the ovariologist and communicated by him to the profession. He could not but thrill with the glorious thought that the operation which he had established was the basis from which they had all sprung.

When he began to do ovariectomy, the literature of abdominal surgery did not exist; the operation was not mentioned in the text-books, nor referred to in surgical lectures in the schools. At the present time, no one man can read in twenty-four hours all the articles published in the same length of time in current medical literature. Sir Spencer published four books. The first volume of "Diseases of the Ovaries, their Diagnosis and Treatment," published in 1865, gives a detailed account of one hundred and fourteen cases of completed ovariectomy, and cases of exploratory incisions and partial removal of tumors. It is an octavo volume of some four hundred pages, and every case is given at great length, some of them covering four pages. It is by far the best of all his books, and an ovariologist can learn more from it than from any other work. No second volume was ever issued. His other works were published later: one, under the same title as his first work, in 1872; another in 1882 entitled "Ovarian and Uterine Tumors"; and one in 1885, on "The Diagnosis and Surgical Treatment of Abdominal Tumors."

To no one surgeon perhaps will it ever be given to do so much for humanity. To have done any operation twelve hundred times is a wonderful thing. It is no exaggeration to say that this great surgeon has added at least one hundred centuries to human life.

If we credit him with one thousand recoveries and allow twelve years on the average, as an expectation of life of each of these recovered patients, we shall have twelve thousand years of life added in the aggregate. Deduct two thousand years for the loss of expectation in the two hundred fatal cases and we have ten thousand years left. This is his direct contribution; indirectly he has contributed much more by his influence, example and teachings.

THE PRACTICAL BENEFITS OF SANITARY LEGISLATION.

It is always gratifying to physicians and sanitarians to see the fruit of their labors in the department of public health, result in the actual diminution of infectious disease and the consequent saving of life. A striking instance of the practical effect of municipal sanitary legislation in the control of pulmonary tuberculosis, a disease so wide and fatal that its control means a great saving of life, is found in the annual report of the New York State Board of Health for 1896. It appears by this report that while the number of deaths in that State from pulmonary tuberculosis during the year 1896 amounted to 13,257, about the average mortality from this disease, there was a material reduction in the number of deaths from this cause in the district including New York City and Brooklyn, the percentage of mortality from it being less than in any previous year for the past ten years. The comments on this decrease in the report are of such great interest and significance that we may be pardoned for making a short extract from it.

"In the congested portions of these municipalities are found the largest percentage of deaths from nearly all infectious diseases, and but slight variations from previous years; but in tuberculosis of the lungs decrease has been steady for the last five years. The only explanation of this gratifying exhibit is in the fact that the local boards of health in these cities have recognized that the disease is due to infection, and have, therefore, taken unusual precautions to prevent its spread by a more rigid scrutiny of the food-supply, especially the quality of the milk and the examination of the cows supplying it, as far as their jurisdiction extends."

The facts thus stated have been presented to the Legislature with a view to securing liberal appropriations for the work of reducing the danger of tuberculosis from infected cattle.

Such evident results as these from the regulation of the milk-supply over a limited area, certainly ought to influence legislators in other States as well as New York, to provide so liberally for the proper examination of cattle, that tuberculosis from infected milk shall no longer seriously threaten any community in our country.

MEDICAL NOTES.

PIGEONS AND THE PLAGUE.—It is reported that pigeons are dying in great numbers of the plague in Bombay, just as the rats have died in former epidemics. They might very properly be termed "carriers" of infection.

THE CZAR PROMOTES MEDICAL EDUCATION OF WOMEN.—The czar has assigned a sum of 65,000 roubles from the imperial treasury for the erection of residential quarters for the female students attending the St. Petersburg Medical Institute for Women. The building will be opened this year.

PROFESSOR NOCARD'S WORK ON TUBERCULOSIS.—The Laclaze prize of the Paris Faculty of Medicine has been conferred upon Professor Nocard, in recognition of his recent work on tuberculosis.

PRECAUTIONS AGAINST PLAGUE.—The governments of England, France, Germany, Austria, Russia and Turkey, have agreed to hold an international conference for the purpose of considering precautionary measures against the spread into Europe of the bubonic plague which is raging in India.

THE BACILLUS OF BUBONIC PLAGUE.—It is reported that Dr. Roux, head of the Pasteur Institute, Paris, has found that the bacillus of the bubonic plague has little power of resistance, and that all antiseptics kill it. It dies at a temperature of 140° F., but it retains vitality in the soil, which is an explanation of the fact that it is never eradicated from Eastern countries.

PLAGUE IN INDIA.—Seven months is the average period during which plague has been found in previous epidemics in a given district, so that no great abatement of the disease in Bombay is to be expected until seven months from the time of the appearance of the epidemic last September. It is reported that the parts of that city in which the plague first appeared, are already enjoying a cessation; and if it be true that the disease was present, though not recognized, last August, the seven months for those districts are nearly at an end.

THE SERUM TREATMENT OF PLAGUE.—Lord Lister in a communication to the *British Medical Journal*, announces that he has the profound satisfaction of being able to state, on the authority of the India office, that the Bombay government intends to make use of the services of M. Yersin in the treatment of persons suffering from plague. M. Yersin is now on his way to the stricken region to give a full trial to his method, and Lord Lister has learned through another channel that before the middle of February the serum treatment will probably have begun in Bombay.

A STEP IN THE RIGHT DIRECTION.—Dr. F. L. Hall, of Perry, Ill., a member of the State Legislature, has introduced the following bill in that body:

A Bill for an act to provide for secrecy in communications between physicians and patients in suits at law or in chancery where the patient is a party in interest to such suit.

SECTION 1. *Be it enacted by the People of the State of Illinois, represented in the General Assembly,* That no person duly authorized to practise as a physician or surgeon shall be compelled or permitted as a witness in the trial of any cause at law or in chancery in this State wherein his patient is a party in interest to such cause, to disclose any information which may be acquired in advising or attending any patient in a professional character, and which information was necessary to enable him to advise or prescribe for such patient as his physician or to do any act for him as a surgeon, unless the consent of the patient to the making of such disclosure is first had and obtained.

THE ANNOYANCES OF EUROPEAN QUARANTINE.—A traveller who arrived at Trieste on an Austrian-Lloyd steamer a few weeks ago has involuntarily acquired a large amount of the sort of fame which results

from the baffling of public curiosity. He was from Bombay, and the Italian authorities were intensely alarmed lest he had brought the bubonic plague along with him. At first they refused to let him land at all, but finally permitted him to do so, on condition that he submit to a dreadfully thorough course of disinfection and would promise to continue his journey in a private car into which he and his baggage should be carefully sealed. To this he consented, and in his prison on wheels, which was placed between the engine and the baggage car, he started for the north. At Udine, the formalities of inspection and fumigation were again carried out. At Verona the process was repeated, and then Milan's officials tried their hands at the work before sending him on towards the Swiss frontier. There they were still more cautious, for they refused to let him enter the republic on any terms whatever. So back to Milan he was taken, still in the sealed car. Here the farce ended, for after a fifth examination and disinfection the man was released and permitted to go where and as he chose.—*Medical News.*

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, February 24, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 87, scarlet fever 39, measles 150, typhoid fever 7.

A BALL IN AID OF THE INFANTS' HOSPITAL.—A brilliant and successful charity ball in aid of the West End Infants' Hospital, Boston, was held in Mechanics Hall on February 16th.

A GIFT TOWARDS A HOSPITAL FOR PAWTUCKET.—Abbie T. Fowler has given to the city of Pawtucket, R. I., property worth \$20,000 to aid in the establishment of a City Hospital.

PROF. T. M. ROTCH ADDRESSES THE NEW YORK ACADEMY OF MEDICINE.—Prof. T. M. Rotch, M.D., of the Harvard Medical School, by invitation, addressed the New York Academy of Medicine on Thursday, February 18th, his subject being "The Use of Modified Milk in Health and Disease." Dr. E. G. Janeway presided. The discussion was introduced by Prof. J. P. Crozier Griffith, of Philadelphia, and Prof. A. Jacobi. They were followed by Drs. L. E. Holt, N. Allen Thomas, W. P. Northrup and J. E. Winters. There was a large attendance. The lecture was illustrated by means of lantern exhibits, charts and blackboard drawings. The evening closed with some very complimentary remarks by the President upon the work done by the reader of the paper. A collation followed.

LEGISLATION RELATING TO CONTAGIOUS DISEASE.—A bill relating to contagious and infectious disease is under consideration by the Massachusetts House of Representatives. The object of the bill is to prevent the building of private sanatoria for contagious diseases in cities and towns. Section 1 of the proposed act

provides that "no infectious or contagious disease or other disease dangerous to the public health shall be treated or cared for in any city or town in any hospital, home, or other like institution, not a public hospital maintained at the expense of said city or town, or of the Commonwealth, or receiving endowment or assistance therefrom; *provided, however*, that the board of aldermen of any city, by unanimous vote, with the approval of the mayor and board of health thereof, and the board of selectmen of any town, by unanimous vote, with the approval of the board of health thereof, may license any private hospital, home or other like institution, of said city or town, to treat and care for any of said infectious and contagious diseases or other diseases dangerous to the public health."

And Section 2 provides that "the following diseases are infectious and contagious diseases and diseases dangerous to the public health within the meaning of this act: small-pox, diphtheria, phthisis or pulmonary tuberculosis, membranous croup, measles, scarlet fever, typhus fever, yellow fever and cholera."

NEW YORK.

DEATH OF DR. JIMENEZ.—Dr. Saturnino M. Jimenez, a well-known Cuban practitioner, died at his residence in New York on February 17th, of pneumonia. He was born in 1851 in Matanzas, Cuba, and studied medicine at the Jefferson Medical College in Philadelphia, from which he was graduated in 1878. He afterwards spent some time in professional study abroad, and in 1882 came to New York, where he succeeded to the extensive practice of Dr. Juan Cisneros. He was a patriotic Cuban and a member of the Marti Relief Association.

PHTHISIS IN THE ADIRONDACKS.—From the report of the State Board of Health it appears that the death-rate from consumption in the Adirondack district increased during the year, and has shown a steady increase for the past five years. This is accounted for by the fact that an increasing number of individuals affected with the disease have been resorting to this region in the hope of relief.

Miscellany.

A CASE OF NUMEROUS HYDATID CYSTS DISSEMINATED IN THE ABDOMINAL AND PELVIC CAVITIES.

CASES of disseminated hydatids are so rare in medical literature that the report of such a case, and especially of one which throws light on their mode of dissemination, is of considerable interest. Such a case is reported by Farrar in the *Quarterly Medical Journal* for January, 1897.

The patient, a small, thin woman, twenty-four years old, had suffered for some time from spasmodic pains in the abdomen, irregular menstruation, and a fetid intermenstrual discharge. For about a year she had noticed the development of "lumps" in the abdomen, which in the beginning were about the size of a walnut.

Two months before entrance she had had an attack of acute abdominal pain with collapse, which had been taken for hepatic colic. When she came under the care of Mr. Farrar, he found the abdominal cavity enlarged, and containing four or five masses, one of which resembled in shape, size and motion, a floating kidney. There was a large, immobile mass in the right lumbar region, just below the liver. The uterus was ante-flexed and held forward by a mass which filled the whole pelvis. The diagnosis was thought to lie between hydatid disease and sarcomatous, or even tuberculous, deposits in the omentum and the pelvis.

Laparotomy disclosed hundreds of hydatid cysts disseminated throughout the abdominal cavity, and lying chiefly in the omentum. The larger masses were shelled out and removed, as were also several pieces of the omentum, but considerable hemorrhage resulted; and after a prolonged operation, the operator was obliged to leave behind the pelvic cyst and the large cyst under the liver, as well as hundreds of smaller cysts, owing to the collapsed condition of the patient. Some of the cysts had clear, and others caseating contents.

The patient recovered from the collapse, and in a few days began to gain. Eighteen days after the operation the wound burst open with a discharge of grumous, offensive pus, and twenty days later there was a discharge of pus from the bladder. The patient gained flesh and strength, and two months after the operation, the cyst in the left hypochondrium was aspirated and three or four ounces of fluid withdrawn.

Three months after the operation fever supervened and a second laparotomy allowed the escape of a quantity of extremely fetid pus from the right side of the pelvis. Six months after operation the patient was fat and well, and the abdominal cavity free from tumors.

In view of the history of the case, Farrar naturally concludes that the attack of supposed hepatic colic two months before he saw the patient was in reality an acute peritonitis due to the rupture of the primary cyst in the liver, which rupture resulted in the escape of its contained daughter cysts, and their implantation in the abdomen and pelvis. The case is a remarkable one in view of the fact that rupture of an hydatid cyst into the peritoneal cavity has heretofore been considered a fatal accident, and also of the fact that operative interference seems to have put a check to the development of the innumerable small cysts which were left in the abdomen at the first operation.

The case cannot, of course, be pronounced cured, until after a much longer time has elapsed, but the fact that a complete check was put to the progress of the disease for six months, is certainly a fact of great interest. There would seem, in spite of the improvement, to be great probability of the ultimate return of the disease.

PATHOLOGICAL RESEARCH AND HUMANITY.

THE following extract is taken from the address of Lord Lister at the opening of the new Physiological and Pathological Laboratories at Belfast, Ireland, on January 20, 1897.¹ After speaking of the value to the medical student of a thorough training in bacteriology, he continues as follows:

¹ British Medical Journal, February 6, 1897.

There is another aspect of a pathological institute which I feel some delicacy in alluding to, because there are some people who take strange views with regard to these matters — exaggerated views. There are people who do not object to eating a mutton chop — people who do not even object to shooting a pheasant with the considerable chance that it may be only wounded and may have to die after lingering in pain, unable to obtain its proper nutriment — and yet who consider it something monstrous to introduce under the skin of a guinea-pig a little inoculation of some microbe to ascertain its action. Those seem to me to be most inconsistent views. With regard to all matters in which we are concerned in this world, everything depends upon the motive. A murderer may cut a man's throat to kill him; any one of you medical students may have to cut a man's throat to save his life. The father who chastises his son for the sake of the good of his morals is a most humane man; a father who should beat his son for the mere sake of inflicting pain upon him would be an inhuman monster. And so it is with the necessary experiments upon lower animals. If they were made, as some people seem to assume, for the mere sport of the thing, they would be indeed to be deprecated and decried; but if they are made with the wholly noble object of not only increasing human knowledge, but also diminishing human suffering, then I hold that such investigations are deserving of all praise. Those little know who lightly speak on these matters how much self-denial is required in the prosecution of such researches when they are conducted, as indeed they always are, so far as I am aware, with the object of establishing new truth. The exercise of a little charity might lead those who speak of us as inhuman to reflect that possibly we may be as humane as themselves.

The profession to which I have the great honor to belong is, I firmly believe, on the average, the most humane of all professions. The medical student may be sometimes a rough diamond; but when he comes to have personal charge of patients, and to have the life and health of a fellow-creature depending upon his individual care, he becomes a changed man, and from that day forth his life becomes a constant exercise of beneficence. With that beneficence there is associated benevolence; and in that practical way our profession becomes the most benevolent of all. If our detractors knew this, common-sense would enable them to see that our profession would not be unanimously in favor of these researches if they were the iniquitous things which they are sometimes represented to be.

I was reading the other day a very interesting account of Pasteur's work on rabies, written by one who was associated with him from an early period (M. Duclaux). It had been established that the introduction of a portion of the brain of a mad dog under the skin of a healthy animal was liable to cause rabies, and Pasteur had reason to believe that it was principally in the nervous centres that the poison accumulated. He felt a very strong desire to introduce some of the poison into the brain of an animal; but he was a peculiarly humane man. He never could shoot an animal for sport. He was more humane than the great majority of human beings; and for a long time he could not bring himself to make the experiment of trephining an animal's skull, and introducing some of the poison of rabies into the brain. He was exceeding desirous of doing it to establish the pathology of the disease, but he shrank from it. On one occasion, when he was absent from home, one of his assistants did the experiment, and when Pasteur came back he told him that he had done so. "Oh!" said Pasteur, "the poor creature! His brain has been touched. I am afraid he will be affected with paralysis." The assistant went into a neighboring room and brought in the animal, which was a dog. It came in frisking about and investigating everything in a perfectly natural manner; and Pasteur was exceedingly pleased, and though he did not like dogs, yet he lavished his affection upon that particular animal and petted it; and from that time forth he felt his scruples need no longer exist.

EUCAIN AS A LOCAL ANESTHETIC IN OPHTHALMIC SURGERY.

NUMEROUS reports of the advantages of eucain over cocaine as a local anesthetic in ophthalmic surgery have attracted a good deal of attention to this drug. It is reported to be about equal in effectiveness to cocaine, and to be free from danger of poisonous effects.

A recent report by Wüstefeld¹ tends to show that it is not as free from ill effects as previous reports have shown. Wüstefeld noted a temporary smarting on instillation of a five-per-cent. solution of eucain followed by injection of the conjunctiva. The anesthesia produced was complete, and lasted about as long as that produced by cocaine.

The statement of Vinci,² that no dilatation of the pupil or disturbance of accommodation resulted from its use was not borne out by the observations of Wüstefeld, who found that in almost all his cases dilatation of the pupil and paresis of accommodation ensued.

Although macroscopically no effect upon the scleral surface was noted (the eye was uniformly protected by a wet cotton compress after the operation), experiments upon animals showed a distinctly destructive effect of the drug upon the scleral epithelium. Microscopical sections of the eyes of a guinea-pig into which eucain had been instilled, and the eye subsequently protected, showed the epithelial cells swollen and lifted out of position, the outer layers being partially desquamated. These results seem to Wüstefeld to militate against the use of eucain as a substitute for cocaine in ophthalmic surgery.

The claim that eucain is entirely without toxic effects cannot be said to have been clearly established. Dr. Thomas H. Shasted of Galesburg, Ill., publishes in the *Journal of the American Medical Association*, the account of a case in which transitory amblyopia followed the employment of a five-per-cent. solution of eucain as an anesthetic for the cauterization of the inferior turbinated bones.

Correspondence.

THE HIGH VOLTAGE CURRENT IN ALVEOLAR INFLAMMATION.

BOSTON, February 18, 1897.

MR. EDITOR: — The generator used was described and figured in the *International Dental Journal* for October, 1896. One electrician has placed the voltage at 57,000, another at 100,000, a third at 250,000. The ampère is equally indefinite. The speed was 1,400 revolutions. The length of the apparently continuous spark was three-quarters of an inch when the machine was tested before use.

The patient held the negative terminal in his hand, the positive covered with cotton against the most painful place on the roof of the mouth. The generator was then started by closing a foot switch placed in the armature circuit. Used in this way there is at no time any sensation from the current. The feeling of great cerebral congestion stopped in fifteen minutes; the severe pain in an hour. The gum which beat visibly like a heart became nearly normal. There was no return of the symptoms.

I describe the method to induce some one to try it in other parts of the body. Yours truly,

WILLIAM ROLLINS.

Deaths reported 2,461; under five years of age 790; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping-cough, erysipelas and fevers) 242, acute lung diseases 502, consumption 309, diphtheria and croup 88, diarrheal diseases 40, scarlet fever 26, typhoid fever 24, measles 22, cerebro-spinal meningitis 18, whooping-cough 18, erysipelas 6.

From scarlet fever New York 17, Boston 5, Chicago 2, Cincinnati and Chelsea 1 each. From measles Chicago 11, New York 9, Lowell and Cambridge 1 each. From cerebro-spinal meningitis Chicago 5, Nashville and Lynn 4 each, Baltimore 2, St. Louis, Boston and North Adams 1 each. From whooping-cough Chicago 6, St. Louis 5, New York 4, Washington, Fall River and Cambridge 1 each. From erysipelas Boston 3, New York 2, Chicago 1.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 13, 1897, TO FEBRUARY 19, 1897.

Leave of absence for four months, to take effect upon his relief from duty at Fort McPherson, Ga., is granted to PHILIP G. WALES, assistant surgeon.

MAJOR ROBERT M. O'REILLY, surgeon, will be relieved from duty as attending surgeon in this city (Washington, D. C.), by MAJOR WILLIAM R. HALL, surgeon, and upon the expiration of his present leave of absence will proceed to Fort Wayne, Mich., for station, relieving LIEUT.-COL. JUSTUS M. BROWN, deputy surgeon-general.

LIEUT.-COL. BROWN, on being thus relieved, will proceed to New York City, and upon the retirement of COL. CHARLES T. ALEXANDER, assistant surgeon-general, May 3, 1897, will take charge of the Medical Supply Depot in that city.

PROMOTION.

CAPTAIN JOHN M. BANISTER, assistant surgeon, to be surgeon with the rank of Major, January 26, 1897.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING FEBRUARY 20, 1897.

R. WHITING, surgeon, placed on retired list, February 15th.

J. C. ROSENBLEUTH, assistant surgeon, detached from the "Raleigh," February 20th, and ordered to the "Massachusetts."

SOCIETY NOTICE.

THE SUFFOLK DISTRICT MEDICAL SOCIETY, SURGICAL SECTION. — The Section will meet at the Medical Library, 19 Boylston Place, on Wednesday evening, March 3, 1897, at 8 o'clock.

At 8.05 p. m. "The Permanent or Later Results of Fracture of the Skull," by Dr. W. N. Bullard. Dr. D. W. Cheever will open the discussion of this paper.

At 8.35 p. m. "Gauze Drainage," by Dr. F. B. Harrington.

At 8.55 p. m. The Presentation of Pathological Specimens by Dr. E. H. Nichols.

At 9.15 p. m. "The Choice between the Abdominal and the Vaginal Incision in the Operative Treatment of Acute Pelvic Inflammations; with some Remarks upon the Technique of the Vaginal Operation," by Dr. Edward Reynolds. Dr. W. L. Bur-
rage will open the discussion of this paper.

PAUL THORNDIKE, M.D., Secretary, 244 Marlborough St.

RECENT DEATHS.

HENRY HARTSHORNE, M.D., University of Pennsylvania, 1845, died at the age of seventy-three years at Tokio, Japan, February 10, 1897. He was at one time professor of practice of medicine in the University of Pennsylvania and later became professor of hygiene in the latter institution.

SAMUEL H. CHARLTON, M.D., of Seymour, Ind., a former president of the Indiana State Medical Society, died January 12, 1897, aged seventy years.

THE PREVENTION OF FLAT-FOOT AND SIMILAR AFFECTIONS.¹

BY R. W. LOVETT, M.D., BOSTON.

THE adult foot of the modern civilized American compares unfavorably, from an anatomical and mechanical standpoint, with the foot of the child or the savage. The child, starting in life with a foot presenting certain definite anatomical characteristics, reaches adult life among savages with a foot but little altered in these essentials; but in civilized life, in practically all cases, with a foot distorted and weakened, and these distortions are more or less uniform. These distortions are so closely allied to the disabling weaknesses of the foot, that their study becomes of interest.

A certain experience among trained nurses which has fallen to my lot, will serve as the text from which to speak.

In April, 1895, I was requested by the Superintendent of the Boston City Hospital to see if any means might be devised to diminish the loss of time caused by the breaking down of the feet of the nurses in the Training School. I undertook the investigation on condition that I might see and examine every nurse coming to the hospital and prescribe a boot for her, just as I would prescribe medicine at a drug store. The work has been conducted in that way, and I have studied with considerable care 160 nurses at that hospital. They probably present a better foot, on the whole, than would the same number of women taken at random in the community, for the reason that the applicants are selected more or less from the point of view of their physical condition, and women of obviously poor development are ruled out. The class of feet that I have seen among the nurses at the hospital, I consider as being fairly representative of the normal foot, as it exists in the women of a highly civilized community.

The distortions that exist among these are practically three: (1) outward displacement of the great toe; (2) crumpling of the toes; (3) excessive pronation of the foot.

OUTWARD DISPLACEMENT OF THE GREAT TOE.

In the foot of the infant and the unspoiled foot of the savage the line of the great toe prolonged backward, should pass through the centre of the heel. This is known as Meyer's line, and indicates the position of the great toe in which the muscles controlling it were meant to keep it. This position practically never exists in the adult civilized foot. In somewhat over 300 feet studied,² comprising those of the nurses, 100 applicants for the position of policemen, and various feet supposed to be normal, the writer has not seen a single adult case where Meyer's line passed through the centre of the heel and in a very large number, the backward prolongation of the great toe did not pass within the border of the heel at all.

The outward displacement of the great toe cripples an important muscle, the flexor longus pollicis, and, by the disabling of the great toe, removes one of the

chief supports of the inner border of the foot, thus predisposing the foot to roll over inward.

CRUMPLING OF THE TOES.

The second distortion consists in crumpling of the toes, which begins in early childhood; under ordinary circumstances and compared to the other two distortions it is of comparatively little importance relatively, from a mechanical point of view.

EXCESSIVE PRONATION OF THE FOOT.

What I speak of as excessive pronation of the foot, for want of a better name, is the most important and the most significant of the three distortions of the foot.

By pronation of the foot I mean the position of weight bearing, the position in which the forward part of the foot is abducted and the inner malleolus becomes more prominent. In the normal foot not bearing excessive weight, the inner border of the great toe, the inner malleolus and the inner condyle of the femur should all be in the same vertical plane. A certain amount of pronation is normal; but in the weak or overweighted foot, the foot is displaced too much outward in its relation to the leg, and by this movement of pronation carried to excess. This condition is often spoken of as "weak ankles" (Fig. 1).

FIG. 1 The position of excessive pronation.

Finally allow me to state it in a mathematical way: Pronation is a compound anatomical movement consisting of abduction of the forward part of the foot plus eversion of the sole of the foot.

It is the position associated with "toeing out."

Pronation is the position taken by tired people; the position which the muscles have the least work to maintain. Excessive pronation is both a separate pathological condition in itself and it is also the early stage of flat-foot. If you will allow me to drop the use of the word excessive, I will speak of the pathological condition simply as pronation of the foot. It varies more, I believe, in proportion to the degree of pain than any other factor; and in the work of which I have spoken, I have worked upon the assumption that the prevention of pronation was, in most cases, the prevention of trouble.

If you will allow me once more to speak of my experience among the nurses. It was obvious when I

¹ Read before the Boston Society for Medical Improvement on December 28, 1896.

² Figures 10 and 11, p. 91, Boston City Hospital Reports, Seventh Series, 1896.

began upon this work in April, 1895, that some record of the condition of the feet was necessary. I adopted the conventional one of imprint tracings. Each nurse stepped upon a smoked cardboard, which was then shellacked and preserved. It has generally been assumed that a certain type of imprint tracings represented the normal foot, and that variations from this

teen inches high, in the top of which a piece of plate glass, about 12×12 inches square has been set; or a glass topped table may be used. Under this table, and facing the light, is a mirror set at an angle of 45° to the floor. In this mirror may be seen with great clearness the reflection of the bottom of the feet, bearing weight. The weight-bearing surfaces appear as

FIG. 2. A record of the non-weight-bearing (in black line) and of the weight-bearing (in dotted line) positions of the foot, drawn on the under side of a glass plate on which the patient stands. The two added together give the ordinary imprint tracing, which is a composite.

type in a general way, represented pathological conditions. It became obvious, after a few months, that the smoked tracings afforded little trustworthy evidence of the real condition of the foot. In one or two cases where the nurses were suffering severe and almost disabling pain, when they first came to the hospital no variation from the so-called normal arch was detected when studied by this method; and after a study of a large series of studies taken in this way, I abandoned this plan, even before I had formulated any other method of record. The reason for this unreliability became obvious later. The feet in touching the smoked pasteboard first record indelibly the non-weight-bearing position and then pass into the weight-bearing position, which is also recorded. If the foot is a weak one and gives way under weight, lying over on its inner side, the smoked tracing may show no noticeable variation from the normal, although the weight is borne by the foot in a wholly abnormal way (Fig. 2).

The difficulty, in short, with the smoked tracing is, that it is a composite record of the non-weight-bearing and the weight-bearing position.

The method of observation and record I adopted, and which I wish to demonstrate, was as follows: The patient stands on a small table (Fig. 3) about fif-

FIG. 3. Table for examination of feet.

FIG. 4. Patient standing on glass table with a mirror underneath. On the mirror is seen the weight-bearing surface of the foot.

teal-white areas, while the line of contact can be seen easily. The distribution of pressure can be estimated by the intensity of the pressure anemia of the skin (Fig. 4).

For record a photograph may be taken of the image in the mirror, or with a soft pencil held perpendicularly to the under side of the glass, an outline of the pressure areas may be traced on the under side of the glass. Then, after the patient steps down, a thin sheet of paper may be placed over the upper surface

FIG. 5.

of the glass and the lines on the under surface may be readily seen through the paper and traced.³

The value of the method lies in the fact that the surgeon is able to look directly at the bottom of the foot, under pressure.

The problems opened up by this method are too new and too complex to be settled by any small number of investigations. One thing, however, may be said; that in the weak foot the outer border of the foot narrows and lifts when weight is borne on the leg and the weight-bearing surface moves inward. In the ordinary foot seen among the nurses, the outer border of the foot in most instances does not touch the ground during weight-bearing, or, if in contact, it bears little weight. In the majority of weak and painful feet examined, it has been obvious that the weight-bearing surface was too far inside.

The problem which I met, in beginning to work upon these nurses, was this: The amount of trouble had been large; nurses had left the school with disabled and broken-down feet; regulation boots had been tried from various shoe-stores, and had not been successful. In 1892 the aggregate loss of time was 42 days. In

1893 the loss of time was 125 days, and one nurse left the school on account of foot trouble. In 1894 the loss of time was 41 days, and one nurse left the school on account of foot trouble. Previous to the adoption of the regulation boots, the superintendent thinks that there was even more trouble than that recorded. Since April, 1895, when I adopted the principle of trying to prevent pronation of the foot among the nurses, no nurse has been off duty for trouble with the feet. The time now recorded is twenty months (January 1, 1897); and it seems to me fair to assume that the method employed is of value and that the element of luck is not enough to account wholly for exemption for so long a time.

The conditions described afford a good test for the utility of any boot. These nurses are on duty from seven A. M. to eight P. M., with the usual time off. They stand or walk on hard-wood floors, and the conditions are not favorable for the welfare of the foot.

There was no boot in the market suitable for use, and one was constructed on theoretical lines to meet the practical need. It has been modified in some ways, and must be still further changed in details, but in every case the boot to be described has been used.

³ Hall: Trans. American Orthopedic Association, vol. ix.

It is of interest, inasmuch as it is the practical demonstration of the application of a theory to meet a practical requirement.

The endeavor has been to prevent excessive pronation by the use of a boot embodying certain principles which are neither new nor original with me.

(1) The inner line of the sole should be straight, or nearly so. In children it should diverge inside of the straight line to allow the maintenance of the great toe in Meyer's line. This requirement is necessary to prevent the displacement of the great toe.

(2) The shank should be fairly high and stiff and not cut away at its inner border, where its support is most needed to prevent the foot from rolling over on its inner side in weak feet. Cutting away of the inner side of this is almost universal in women's boots. As a rule the shanks of boots are too low, especially this is to be noticed at their inner edge and one improvement to be made is so to manufacture the boot that the shank shall be oblique, highest at its inner border and sloping from that downward.

(3) The sole of the boot should be as wide as the foot opposite the great-toe joint. It is not necessary to demonstrate that, for proper weight bearing, the ends of the metatarsal bones should be free to spread out and not to be crowded one over the other. This width of the foot is the most difficult thing to obtain, not only on the part of the wearer, but from the maker. At the hospital all boots are rejected at once, where an outline tracing of the sole of the shoe is not practically as wide as the outline tracing of the bare foot, with weight borne upon it.

What this pressure does may be seen in the radiograph taken by the kindness of Dr. E. A. Codman, of a model standing in one bare foot and one boot. The overlapping of the metatarsal bones should be especially noted (Fig. 5).

(4) The forward part of the sole should diverge inward from the long axis of the foot. That is, it should be made to hold the foot in an adducted position. This is because the prevention of abduction of the forward part of the foot is the prevention of pronation, because the position of adduction is the position of strength and of muscular activity. Holding the foot adducted tends to throw the weight onto the outer border of the foot and to preserve the arch.

When it is seen through the glass that the weight is borne too much on the inner part of the sole, some means, more than adduction of the boot is necessary, and among the nurses I have the inner side of the sole and heel made one-eighth or one-fourth of an inch thicker than the outside, whether they complain of trouble or not, using this in addition to the adducted boot to prevent pronation of the foot.

I have reserved to the end what seemed to me to be, on the whole, the most important part of the subject, namely, the use of a boot for children which shall be of the same shape as the human foot, a boot which conforms to the principles already laid down. I need not do more than comment before this audience on the manifest injustice of making children wear shoes of the ordinary symmetrical pattern, favoring those distortions of the foot which lead to weakness and to mechanical disadvantage and perpetuating the present condition of distorted feet. If persons who have reached years of discretion choose to wear boots which are unreasonable and harmful, they have a perfect right to do so; but children should at least have the chance

given them of reaching years of discretion with their feet comparatively undistorted, to be spoiled later if their inclinations lead them to do so.

Finally, the prevention of disabled and disabling feet is, I believe, in general to be attained by the use of a boot holding the foot in its position of greatest mechanical strength. The prevention of excessive pronation by adducting the forward part of the foot and preventing eversion of the sole of the foot is, I believe, the means by which this is to be done in general. And if you choose to make a wider application of my work among the nurses, the purpose of this paper will have been accomplished.

HERNIA EPIGASTRICA, WITH A REPORT OF CASES.

BY HOWARD A. LOTHROP, A.M., M.D.,
Assistant in Anatomy, Harvard University.

(Concluded from No. 8, p. 178.)

Anatomy.—A study of the regional anatomy in dissecting-room subjects has rendered the suppositions of Cloquet and Witzel more comprehensible, and has suggested possibilities which may be of value in understanding the mechanism of the formation of epigastric herniae. Limiting our description to the area included in the definition given above, we reach the external abdominal aponeurosis after passing through the skin, subcutaneous fat (very variable in thickness), and the superficial and deep layers of connective tissue. The fibres of this aponeurosis, derived from the external abdominal muscle, arising just outside of the linea semilunaris, pass downward and inward, forming an oblique angle with those of the opposite side at the linea alba, and are continued beyond a short distance on either side. The tendinous fibres derived from the internal oblique muscle split into two layers at the linea semilunaris, one of which passes inward and upward to the linea alba forming a strong fibrous sheath, anterior to the belly of the rectus abdominis muscle. This double sheath is practically one layer in that the oblique fibres derived from these two muscles cross each other at an angle and are more or less intricately united by inosculating fibres which continue their original direction and thereby form rhomboid meshes. The posterior sheath of the rectus in this region is formed by the union of the posterior division of the internal oblique aponeurosis with the tendon of the transversalis muscle. As in the anterior sheath, these fibres cross and inosculate so as to form similar meshes, and join in the linea alba with the corresponding fibres of the opposite side together with the fibres of the anterior layers.

The linea alba, therefore, is a comparatively thick and very dense mass of oblique inosculating fibres, crossing in two directions. It is narrowest below the umbilicus where the bellies of the recti muscles are in fairly close apposition, wider above, and toward the xiphoid cartilage its width may be considerable. In this line, no muscle tissue intervenes between the skin and peritoneum. The lineæ semilunares mark the division of the tendon of the internal oblique muscles, separated above at their origin, near the tip of the ninth costal cartilage, by the recti muscles, below they join the semilunar fold of Douglas. The tendon of the transversalis muscle may arise external or considerably internal to the lineæ semilunares, so that in

these lines we may have only fibrous and fat tissue between the skin and peritoneum, as is invariable in the median line. The tendons are generally broader in subjects poor in muscle tissue.

The recti muscles are crossed anteriorly by three transverse zigzag tendinous intersections. The lower one, opposite the umbilicus, is only superficial, the middle one, half-way from the umbilicus to the xiphoid cartilage, sometimes includes the thickness of the muscle, so that in this line, also, the abdominal wall

FIG. 1. Showing general direction of fibres of aponeurosis of (1) external and (2) internal oblique muscles as they cross and pass beyond the linea alba. Left rectus sheath removed anteriorly. (3) Rectus abdominis.

may be deficient in muscle tissue. The superior linea transversa is in close proximity to the cartilages of the ribs and the tendinous insertion of the muscles. This area just below the end of the sternum is frequently devoid of muscle tissue, and protected by fairly tense fibrous tissue stretched between the rigid edges of the thorax, consequently a well directed trauma might result in laceration.

Lying between the abdominal muscles and the peritoneum is the fascia transversalis, a thin layer of connective tissue which is of little account in the epigastric area, but closely associated with it is the subperitoneal fat layer, which plays a very important rôle in the formation of epigastric herniæ. This fat layer may be a quarter of an inch thick and line the whole epigastrium, or it may be almost wanting, but it is invariably present in the shallow depressions corresponding to the linea alba, lineæ semilunares and transversæ. The peritoneum is nowhere firmly attached, but is everywhere loosely connected by delicate fibres to the layers in front, forming areolar spaces which are more or less filled with fat.

Normally in the adult, a cord passes upward from the umbilicus, in the abdominal wall, just posterior to the transversalis muscle, roughly parallel to the linea

alba. At a variable point, generally a little below the centre of the distance between the umbilicus and xiphoid cartilage; it leaves the abdominal wall and passes upwards and backwards and to the right to the under surface of the liver. This is the round ligament of the liver, the remnant of the fetal umbilical vein, it is questionable whether it ever remains patent, as some maintain, but is not rarely found as a cord complicating these herniæ (Case II). The peritoneum is reflected over the round ligament, so as to

FIG. 2. Showing direction of fibres of aponeurosis of (1) transversalis and (2) internal oblique muscles forming (3) posterior rectus sheath, and inosculating at the linea alba with all the fibres of the anterior sheath so as to form a dense mass. form the falciform ligament of the liver, in the free edge of which are the parumbilical veins (Sappey, Luscha), which are occasionally found considerably dilated, and this round ligament. Accumulations of fat are very constant where the falciform ligament is joined to the abdominal wall, and pockets in the peritoneum are very common here. Lastly, there are small perforations in all the abdominal layers of the epigastrium, for the transmission of vessels and nerves, which are frequently distended with fat according to the nutrition of the patient.

PATHOLOGICAL ANATOMY.

By the term hernia, we mean the protrusion of a portion of the abdominal contents through an opening in the abdominal parietes. These openings may exist normally, and predispose to hernia, as in the femoral and inguinal variety; they may be the result of trauma, causing a rent in strong tendon or muscle; or finally may develop slowly in consequence of the atrophy of fat or muscle, particularly along the course of vessels. In the epigastric area, there are no preformed openings, therefore the hernia must make its way through a rent in the tissues, or gradually force a passage along the course of vessels, especially

if favored by atrophy of fat tissue. A common point of origin for these herniæ is where the round ligament and parumbilical veins leave the abdominal wall, on their passage to the liver, which is also in the vicinity of the middle linea transversa.

On considering the arrangement of the fibres of the tendons of the broad abdominal muscles, it will be seen that their meshes are kept closed when these muscles are in action, but that force tending to overextend the trunk will tend to open these meshes and may result in an oblique rent in their continuity (Case I). Owing to the great density of the linea alba, this rupture generally starts just to one side of the median line, as is verified by careful observation while operating. Now, as first pointed out by Cloquet, when once there is a small rent in the fascia, the abdominal pressure forces a small portion of the semi-fluid and pliable subperitoneal fat through the slit, both of which slowly enlarge and the slit gradually becomes oval. In the dissecting-room, and at operation, it is very noticeable how readily this fat protrudes when the fascia is nicked. The delicate fibres connected with the peritoneum in the line of the vessels or which bind it to the fascia transversalis, tend

is not aware of its presence. Its growth is very gradual and it is seldom larger than an English walnut. In cases of long standing, there is always a certain looseness of the skin to be observed over the site of the hernia, even when reduced (Case II).

(3) Number. One hernia is the rule, two are unusual, and Nelhues, Pantzer and Witzel have observed three, and Berger four herniæ existing simultaneously in the same patient.

(4) Abdominal Layers. These consist of: (a) skin; (b) superficial fascia; (c) deep fascia; (d) fascia transversalis, often containing subperitoneal fat in its meshes; (e) peritoneum.

(5) The Sac is often overlooked on account of its thinness, or it may be discovered only after the excision of an obscure mass of fat, passing into which is a blind pouch. The sac passes through the ring and is there continuous with the peritoneum, and along the neck may be fat in continuation with the subperitoneal fat.

(6) The Ring is an oblique slit with sharp edges in early cases, but in time it becomes oval or round. It is usually too small to be detected with much degree of certainty through the skin.

(7) Contents of Sac:

(a) Very rarely the neck of the sac becomes obliterated with consequent cyst formation in the distal portion.

(b) The omentum is by far the commonest organ present within the sac which it is more or less adherent in most of the cases, particularly around the ring and on its under surface. Hence these herniæ are only partially reducible either in consequence of adhesions, or as a result of hypertrophy of lobes of omentum already within the sac. This fixation of the omentum is responsible for most of the symptoms.

(c) Intestine occasionally enters the sac, and may have been a complication in Case II, but authorities differ as to whether colon or small intestine is the commoner. Greiffenhagen has published the only authentic case of strangulation.

(d) The falciform and round ligaments may be complications (Case II, Lucas-Championnière) and this can be readily understood from the local anatomy.

(e) The earliest writers believed that the stomach was invariably associated with these herniæ, hence their term "gastrocele," but there is no very reliable evidence to show that this organ is ever involved.

SYMPTOMS.

For the sake of description, the clinical history of these cases allows us to consider them under three groups:

(1) On making a careful physical examination for some cause or other, a small tumor is accidentally detected in the epigastrium, which may or may not have been noticed by the patient. Such a tumor is generally slightly tender on palpation, but otherwise it is free from causing subjective or objective symptoms. It is generally made up of subperitoneal fat containing a prolongation of peritoneum. It may remain thus for years, or at any time become the source of severe suffering.

(2) By far the great preponderance of cases arise insidiously, continue a chronic course, with slowly increasing severity of symptoms, and with no hope of spontaneous relief. Symptoms referred to the stomach first attract the attention of the patient and the

FIG. 4. Showing comparative density of (4) linea alba. Lateral tension tends to close the meshes, vertical tension to open them just to one side of the linea alba. (1) External oblique muscle. (2) Internal oblique muscle. (3) Transversalis muscle.

to drag a portion of the peritoneum through the ring after the fat mass, and thus we have the beginning of a hernial sac the outer surface of which may be covered with this layer of fat. This condition has been found repeatedly at operation, was present in Case I and may be the condition in Case IV. When once this peritoneal pouch has been formed, the entrance of omentum or gut is readily understood. The case of Witzel of triple hernia, cited above, is a most convincing example of these transition stages.

In brief, the considerations pertaining to the tumor and its immediate surroundings are as follows:

(1) Location. Commonly just to one side of the linea alba along the lower half of the distance between the xiphoid cartilage and umbilicus, and just below the cartilage. It may appear at any of the tendinous intersections already described. The axis of the tumor may be in any direction.

(2) Size. It may be too small to be detected, but has never been reported larger than an average apple. Ordinarily, when patients are seen for the first time, it is too small to be seen on inspection, and the patient

physician. There is but little characteristic in them, they usually persist for years with varying intensity, and are but little amenable to internal medication. The patient learns sooner or later that it is better not to indulge in hearty meals, and to rest after eating. Gastric symptoms of some sort are present in eighty per cent. of all cases of epigastric hernia. They are more marked after eating and are manifested as eructations, nausea, sense of weight in the epigastrium, and pain. The appetite becomes variable, and vomiting may follow the nausea, the vomitus consisting of ingesta, mucus and bile. Vomiting is often a source of relief. The bowels are generally constipated.

The pain experienced in these cases generally comes on after eating, particularly if the patient moves about, and centres in the epigastrium whence it may radiate in any direction. During digestion there is a dull dragging sensation which may be supplemented by severe, sharp, spasmodic cramps known as "crises"; these compel the patient to remain absolutely quiet in bed. All motions of the body, and coughing, sneezing and vomiting augment the pain, but relief frequently follows the vomiting, in consequence of the removal of so much weight. Drugs, other than morphia, avail nothing. The gastric symptoms are probably due to the pull of the omentum on the stomach, consequent on its fixation in the hernia, which will explain the severity of the symptoms when the stomach is full, or as the result of movements of the body. Hence the value of emptying the stomach or assuming any position which will tend to reduce the hernia. Some are relieved by lying on the back, for the hernia becomes reduced and the tension removed; others have learned to lie on the abdomen and thus remove the tension. If the hernia is irreducible, this is their only alternative.

Pain and gastric symptoms very frequently accompany the protrusion of the subperitoneal fat without omental complication. Various explanations are offered, but it is sufficient here merely to mention the minute and intricate anastomoses between the thoracic, phrenic and sympathetic nerves.

In time, a new chain of symptoms may appear, consequent on mal-nutrition, as a result of frequent gastric disturbance. The patient visits one physician after another with the hope of obtaining relief, becomes worried and anemic, loses weight and strength, and not rarely becomes hypochondriacal. Meanwhile, the attacks of pain become more frequent and alarming in that they have been mistaken for peritonitis and intestinal obstruction, while the only apparent external sign may be a very small tumor in the epigastrium, which will be overlooked unless its presence is suspected.

As regards the tumor, there is little more to be said, except that all gastro-intestinal cases should suggest the possibility of an epigastric hernia. The patient should be seen at different times, examined in different positions, with the abdominal muscles tense or flaccid, and an impulse looked for on cough.

Jaundice has been recorded six times as a complication in these cases, where at operation, the gall bladder and ducts were normal. Two cases were operated for gall-stones, and these were considered as a possibility in Case II. In all cases, there was an adherent omental hernia, the tension of which may have obstructed the gall ducts at times. All cases were relieved of this complication by the operation.

(3) This group contains a few well-authenticated cases where the symptoms follow immediately after some trauma as described above. The injury is often sufficient to cause complete collapse, followed by vomiting and epigastric pain and tenderness, sufficient to keep the patient in bed. Gradually these very acute symptoms pass off, and the patient may or may not recover his usual health, but in either case he finds that he is very subject to what he terms "dyspepsia." He dates all of this trouble from the time of injury, and the further history of the case corresponds to that described under Group 2. On several occasions, the tumor has been noticed as early as three hours after the injury, although usually its discovery is a matter of months or years. Two cases have been diagnosed by subjective symptoms and operated successfully, where the hernia was too small to be detected on account of a well-developed panniculus adiposus (Wild, Niehues). There is no sure means of differentiating subperitoneal fat tumors from omentum before operation; both may give rise to precisely the same subjective and objective symptoms and demand the same treatment. Bohland states that in ten per cent. of all cases, the stomach becomes dilated from atony.

DIFFERENTIAL DIAGNOSIS.

It will suffice at this time merely to mention the lesions which must be considered in this connection, remembering that most errors in diagnosis are attributable to neglect to make an accurate physical examination. Such an examination is of primary importance in all gastro-intestinal cases, at different times and in different postures. An enumeration of diseases which may be grouped in this connection is as follows:

- (1) Diseases of the stomach: gastralgia, ulcer, carcinoma, catarrhal
- (2) Biliary calculus, inflammation of the gall-bladder.
- (3) Renal calculus.
- (4) Caries of sternum, with the abscess over xiphoid cartilage or just below it.
- (5) Dermoid cysts.
- (6) Gumma.
- (7) Simple lipoma arising anterior to the abdominal aponeurosis.
- (8) Epigastric hernia, containing subperitoneal fat, omentum or gut, singly or any combination of these structures.

COURSE.

Most of these cases run a comparatively mild course for years with occasional gastric "crises," which are apt to increase in severity and frequency, until finally, the general health and mental condition of the patient suffer. Adhesions augment the severity of the case, give rise to incarceration, but very rarely strangulation, and occasionally are peritonitis and intestinal obstruction suspected. A most striking feature is the great severity of the subjective symptoms when compared with the objective signs.

PROGNOSIS.

When these cases are left to run their own course, the outlook is unfavorable, for many of the patients become hopeless invalids, and it has never been demonstrated that spontaneous recovery ever takes place.

As a rule, relief is immediate after operation, and a permanent recovery is to be expected. Recurrences are now rare, and are to be attributed to faulty tech-

bique. In a few cases of long standing, which have resulted in serious derangement of the nervous system or in organic changes consequent on mal-nutrition, the prognosis is unfavorable.

TREATMENT.

(1) Palliative. Numerous devices have been used for the retention of these troublesome hernia, but their efficacy has been anything but satisfactory. From the fact that these hernia are so commonly irreducible, any truss serves only as an irritant, becomes unbearable, and makes the patient's condition worse. The adhesions become more extensive, and a local peritonitis not rarely follows. Hence palliative treatment should never be recommended unless some valid contra-indication exists for any radical operation, such as some serious organic lesion or advanced age. Under such circumstances, carefully adjusted swathes with or without a pad, as experience with each case will dictate, may serve to alleviate suffering in some cases. In women, carefully adjusted corsets are occasionally effective. The diet should be regulated so as to avoid overloading the stomach, and the importance of bodily rest after eating should be enjoined upon the patient.

(2) Operative. Many of the early operated cases died of peritonitis. Some years later, deaths were less frequent, and absolute relief was afforded by the operation, but recurrences generally took place because these wounds were left open and allowed to heal by granulation.

Under the present technique of abdominal surgery, the risk of death is practically nothing, the almost immediate relief from symptoms assured, and the chance of recurrence very slight.

The general steps in operating do not differ essentially from those to be followed in any case of hernia. The sac should be carefully isolated deep within the ring, then incised and its contents examined, adhesions freed, redundant omentum excised, and the stump reduced within the abdominal cavity. It is safest to enlarge the ring sufficiently to introduce the finger in order to be certain that no further adhesions exist around its circumference. Such adhesions very commonly exist, and these alone are sufficient to give rise to all the symptoms which the case presents. The entire sac should be excised and the peritoneum closed with slight tension so as to obliterate all folds. The abdominal wall should be closed in layers by buried sutures, and the whole may be supported by a few deep interrupted silkworm-gut sutures. Muscular tissue is one of the best barriers against recurrence, hence it may be advantageous to open the sheaths of the recti muscles laterally, and thus obtain perfect approximation along the line of incision.

CONCLUSIONS.

(1) That hernia epigastrica should be considered in the differential diagnosis of gastro-intestinal disorders in all text-books which deal with internal medicine.

(2) That cases are probably more common than is generally supposed.

(3) That the apparent gravity of the symptoms is far out of proportion to the physical signs.

(4) That in most cases the gastro-intestinal symptoms are probably consequent on tension or constriction of nerve fibres in the omentum and peritoneum.

(5) That the subperitoneal fat tissue plays an important rôle in the formation of these hernia, the

presence of which alone may give rise to symptoms and signs differing in no respect from cases complicated by the presence of omentum or intestine.

(6) That palliative treatment is practically useless, and should be considered only in exceptional cases.

(7) That operative treatment offers immediate relief with a minimum of risk.

FIVE CASES OF ECLAMPSIA, WITH COMMENTS UPON THE TREATMENT.¹

BY A. WORCESTER, A.M., M.D., WALTHAM, MASS.

CASE I. Eclampsia following delivery. Recovery.

A primipara, twenty-two years old, after a day of pain which she had concealed, was finally forced to admit her illegitimate pregnancy by the gush of liquor amnii at 5 p. m., December 15, 1885.

At 9 p. m. I found her in a dazed, stupid condition. Her face was decidedly edematous. She had not been passing much urine for some days. After the birth of a six-pound girl at midnight, and in fifteen minutes the delivery of the placenta, she was seized with a convulsion. In fifteen minutes a second occurred, and

¹ Read before the Obstetrical Society of Boston, December 15, 1896.

a third a half-hour later. For several hours she was comatose. During the following afternoon she had several convulsions, finally controlled by the hypodermic injection of a half-grain of morphia, and by the forcible police removal, at my request, of the lady of the house, who persisted in upbraiding the patient for damaging the reputation of the premises.

CASE II. Eclampsia during labor. Recovery.

On June 10, 1887, I found Mrs. S. F. Z. in a most wretched condition. She had previously borne five children without trouble. For several weeks she had been suffering from headache, and for several days she had been having occasional labor pains. The os was not larger than a silver half-dollar, the lips were wiredged. She was vomiting often. Her urine was very scanty, and dark brown. Cream-of-tartar water was given her. A few hours later, during my absence, the five-pound boy was born during a convulsion, and without the nurse's knowledge. Four hours later a second convulsion seized her. The room was then made very hot, and free perspiration obtained. Morphia, half a grain, was given hypodermically to quiet her. After a long sleep she appeared as well as ever, and made an uneventful recovery.

CASE III. Eclampsia. Manual dilatation, podalic version, recovery.

Mrs. C. H. was a primipara twenty-four years old. She was seven months pregnant. One evening she complained of headache. Her feet were much swollen. Her urine contained a trace of albumin, and had not been noticed to be scanty. The next afternoon she vomited, became blind, and soon was in a spasm. She had barely recovered consciousness half an hour later, at the time of my arrival. Immediately there came a second spasm, and in ten minutes a third. She was then etherized and manual dilatation begun; but it was a full half hour before even one finger could be inserted, and nearly two hours before dilatation was completed. Then, by podalic version, a two-pound girl was delivered. The baby lived only for a few gasps. The patient was superheated by means of hot-air from a lamp-chimney carried through a stove-funnel into her bed, and was soon copiously perspiring.

She made a rapid and uninterrupted recovery, but has since had to undergo operation for the repair of her cervix, which was torn through into the vaginal vault.

CASE IV. Eclampsia following labor. Recovery.

Mrs. B. O., a strong, healthy primipara, several hours after a perfectly normal labor, was seized with a convulsion, and became comatose.

I saw her, in consultation. Her urine, drawn by catheter, solidified on boiling. Nitrate of pilocarpine was given hypodermically, and hot air carried directly into her bed. She soon perspired freely. The next day she became conscious, and subsequently made an uninterrupted recovery.

CASE V. Eclampsia without spasms. Partial suppression of urine, recovery.

On September 20, 1896, I found Mrs. B. I. J. suffering with a snapping headache which had lasted for several days, preventing her from sleeping, and which had now become unbearable. She had passed through a former pregnancy nine years before normally, save for a severe post-partum hemorrhage. Now her hands and face as well as her feet and legs were very edematous. Her urine was scanty, and contained one-quarter per cent. albumin with hyaline and granular casts in abundance. She was eight months pregnant.

Phenacetine gave her some relief from the blinding headache. Her bowels were freely moved with Seidlitz powders. Cream-of-tartar water and coffee increased the flow of urine for a time. But soon, on account of her constant vomiting and agonizing headache, morphia and pilocarpine were used hypodermically. But after free perspiration she would be comfortable for several hours. But she was unable to lift her head from the bed. She slept only in naps of a few minutes' duration. She became very restless, and her eyes and face were constantly twitching.

Preparations were made for the induction of labor, but from day to day this was postponed. For ten days she passed only 126 ounces of urine; on one day only 10 ounces; and only 18 ounces the best day.

During each of these ten days she was given at least five pints of liquid nourishment and water. Dinretin, in ten-grain doses every four hours, was given without any apparent effect. But she gradually grew more comfortable; and quite suddenly, after several days' use of Basham's mixture, she began passing more urine, the daily amount jumping from 20 ounces to 37 ounces, and then to 73 ounces. The edema lessened greatly. All medicine was stopped. During the following three weeks she passed sufficient urine, the least amount being 40 ounces. Her appetite returned, and she was able to sit up for a few hours nearly every day, but her headache continued and she slept very poorly.

As her confinement drew near, she became worse again. Her urine amounted to only 163 ounces for the week immediately preceding her labor, to nine ounces the day before, and to eight ounces the day of her labor. The edema returned, together with the severe headache and vomiting. Bromo-cafein was given in large doses, and morphia occasionally. Basham's mixture was again employed.

On October 28th she passed through a normal labor, and gave birth to a large boy. On the following day she passed four pints of urine, and the diuretics were omitted. Her convalescence was rather slow; but she was able to nurse her baby, and she made a perfect recovery. When the baby was a fortnight old her urine again became scanty, one day amounting to only one pint. The headache and vomiting also returned, but under the same diuretic treatment she again rapidly improved. At the end of a month the urine became normal in amount and entirely free from albumin.

She is now (two years later) a perfectly well woman, and her baby is a perfectly well boy.

In previous papers read before this Society and already published² I have reported six other cases of eclampsia, making eleven cases which have occurred in my seven hundred midwifery cases. In four of the eleven cases the mother died. In four cases the premature child died. In two cases the fetus was macerated. In only five cases the child survived.

Inasmuch as both the mother and child lived in the four cases where the labor was neither induced nor assisted, the treatment employed demands close scrutiny in accounting for the frightful mortality.

Two of the four mothers who died were under my own observation for some time previously. Had they been as carefully watched and as faithfully nursed as was my patient last reported (Case V), I cannot but believe they and their babies would have lived. And

² Boston Medical and Surgical Journal, vol. cxx, p. 427; vol. cxxv, p. 28, and vol. cxxxv, p. 353.

I also believe the same of another of the mothers whom I saw only in consultation. The fourth mother who died had not been under medical observation. She died probably from shock or from etherization or from hemorrhage, or, in other words, from too energetic treatment. Her baby survived.

Four premature babies were practically sacrificed where forcible induction of labor was employed, on the supposition that such treatment alone would save the mother's life. Twice this may have been true, but in two of these cases not even the mother was saved. In all the cases fortunately the father survived.

It may be presumptuous to attempt any deductions from such a record as to the proper treatment of eclampsia, especially as it is customary to base recommendations as to treatment only upon uninterrupted successes. Nevertheless, believing as I now do that the treatment employed was not theoretically right, I offer the following criticisms and conclusions:

(1) It is more important to keep account of the amount of urine excreted by pregnant women than it is to test it occasionally for albumin. And if the amount is scanty, prompt measures should be taken to promote diuresis; failing which, then catharsis and diaphoresis should be induced.

(2) In cases of eclampsia, before term, diaphoresis should be tried before resorting to the induction of labor. Hot air is the safest and most effective means thereto.

(3) In cases of eclampsia occurring at term, diaphoresis should be employed *while* inducing and expediting delivery.

(4) The rapid induction of labor by manual dilatation of the cervix is a difficult and dangerous operation, which if combined with forcible delivery of the child is well calculated to add to the shock already caused by the eclamptic attack.

(5) In eclampsia, as in all other cases of kidney failure, ether is contraindicated. Surgical anesthesia is not needed. Chloroform, always the proper anesthetic in obstetric practice, is imperatively proper in cases of eclampsia.

PUERPERAL ECLAMPSIA.¹

A STUDY OF ONE HUNDRED AND SIXTY CASES OCCURRING AT THE BOSTON LYING-IN HOSPITAL AND IN THE PRIVATE PRACTICE OF MEMBERS OF THE OBSTETRICAL SOCIETY OF BOSTON.

BY CHARLES W. TOWNSEND, M.D.,

Physician to Out-Patients, Massachusetts General, Boston Lying-in and Children's Hospitals.

THE following paper, which is offered as an introduction to the discussion of this subject before the Obstetrical Society of Boston, consists first, of a brief analysis of the 67 cases of eclampsia that have occurred at the Boston Lying-in Hospital in the last twelve years, and, secondly, of an analysis of 93 cases occurring in private practice collected from the members of the Society and their invited guests.

I. SIXTY-SEVEN BOSTON LYING-IN HOSPITAL CASES.

I have availed myself of the excellent paper by Dr. Charles M. Green published in the *American Journal of Obstetrics*, Vol. XXVIII, No. 1, 1893, for the cases

of eclampsia occurring at the hospital from 1885² to 1892, inclusive, a total of 36 cases. In the four years (lacking one month) since then, 31 more cases of eclampsia have occurred at the hospital, making a total of 67 cases; 48 of these, or 72 per cent., were primiparae. Of the 67, 48 recovered and 19 died, giving a maternal mortality of 28 per cent.

This compares favorably with other statistics. Thus, Fothergill puts the mortality at 26 per cent.; Braun, of 73 cases, finds it to be 26 per cent.; Dohrn, of 747 cases, 29 per cent.; Dorland, 30; Kaltenbach, 30; Hofmeier (104 cases) 32.4; Shauta, 36.5; Bailly, 42; Madame La Chapelle, 50; Pajot, 50.

The fetal mortality in the ante-partum and inter-partum cases, excluding the non-viable cases, is 24 per cent. out of 32. The following table shows the relative frequency and mortality in the three classes of puerperal eclampsia:

	Cases.	Per cent.	Per cent. fatal.
Ante-partum eclampsia	29	43	38
Inter-partum eclampsia	17	26	23
Post-partum eclampsia	21	31	19

It is seen that the ante-partum cases are the most common and the most fatal; the inter-partum cases are less fatal; while in the post-partum cases the prognosis is the best. Coming now to a more particular consideration of the prognosis, we find that where marked coma was present, always considered an unfavorable sign, about one-half only, or 51 per cent., were fatal.

The average total number of convulsions in the 48 mothers that recovered was 5, the numbers running from 1 to 25. In the 19 that died, the average was 8.2, the numbers running from 2 to 24. It is, therefore, impossible in any given case to form a definite prognosis from the number of convulsions or the existence of coma, as a study of these cases shows that women have died after two convulsions and recovered after 25 and deep coma, although the general rule is, the fewer the convulsions, the better the prognosis.

The effect of the convulsions, or the condition which causes the convulsions, on the child, is also of interest. It is generally assumed that the toxemic condition with eclampsia and coma is, if prolonged, fatal to the child. The Lying-in Hospital cases do not bear this out. Thus, of 19 ante- and inter-partum cases (excluding the non-viable) that recovered, the number of convulsions in the mother averaged 4.8; of seven that died, the convulsions averaged 3.8. One child was born dead after only one maternal convulsion; while four children survived eight or more maternal convulsions, one surviving seventeen maternal attacks and was delivered alive while the mother was comatose. Forced delivery by version is, of course, responsible for the death of the child in several cases, without reference to the existence of toxemia. These cases, therefore, show that it would be unwise to assume that the child was dead even if the mother had had numerous convulsions and was comatose.

The treatment, to quote freely from Dr. Green, in these hospital cases has been essentially the same in all the cases, with minor differences owing to the member of the staff in charge, or adapted to the individual case. It should be remembered that the hospital patients are not received prior to the onset of labor; hence there is no opportunity to observe or relieve the various prodromal symptoms of eclampsia

¹ Read before the Obstetrical Society of Boston, December 15, 1896.

² Cases prior to 1885 are not included, as the aseptic system was not introduced until this date.

and thus to mitigate the severity of the attack or to entirely prevent it.

Moreover, it is the policy of the hospital to admit every case of eclampsia unless the patient is obviously moribund, and this latter rule is sometimes overlooked. Hence all of the anti-partum eclamptic cases were brought to the hospital after one or more convulsions, many of them after a dangerously long delay. Therefore, one would not expect as good results as in those watched in private practice and seen early in the disease.

In brief, the treatment has consisted of the following measures:

In *Ante-partum* cases, if the fetus is not yet viable, and the convulsions are few and mild, the attempt has been successful in a few cases to arrest the convulsions and restore the action of the kidneys by medical measures presently to be enumerated. In the majority of cases interference with pregnancy is practised by manual dilatation of the os and immediate delivery, generally by version.

In *Inter-partum* cases, labor is expedited by forceps, manual dilatation of the os and version being sometimes necessary.

In *Post-partum* cases the following medical measures are resorted to, which are also used to supplement or take the place of obstetric interference in the other classes: Ether during the eclamptic seizures and during artificial delivery. Hot-air bath or hot-water bottles, to excite the action of the skin. Pilocarpine, in doses of one-sixth of a grain, is often given subcutaneously. Elaterium or croton oil, the latter if the patient is comatose, to excite the action of the bowels. Acetate of potash and cream-of-tartar water as diuretics. Chloral and bromide by enema in some cases as sedatives. Morphine is not used, and venesection has been employed only a few times, although post-partum bleeding is encouraged rather than quickly checked.

II. NINETY-THREE CASES OF ECLAMPSIA FROM PRIVATE PRACTICE.³

It seems to be a common impression that the mortality in hospital cases of eclampsia is higher than in private practice for two reasons: first, the patients are not seen until eclampsia often of some duration is actually in progress, no prophylactic measures having been used to mitigate its course; secondly, many desperate cases are sent to the hospital as a last resort. I was therefore somewhat surprised to find that the mortality in private practice was exactly the same, 28 per cent., 67 having recovered and 26 died of the 93 cases. The fetal mortality, 21 cases where this was noted, and the infant was viable, was 43 per cent., nearly twice as great as at the hospital; but the numbers are too few to draw any conclusions.

The relative frequency and mortality in the three classes of puerperal eclampsia, corresponds fairly well with the hospital statistics, except that the post-partum cases are less frequent and more fatal than the inter-partum cases, as will be seen by the following table:

	Cases.	Per cent.	Per cent. fatal.
Ante-partum eclampsia . . .	55	59	33
Inter-partum " . . .	22	24	18
Post-partum " . . .	15	16	26

³ The members furnishing cases are Drs. J. G. Blake, W. E. Boardman, F. H. Davenport, G. J. Engelmann, E. Reynolds, J. P. Reynolds, A. D. Sinclair, C. E. Stedman, J. B. Swift, C. W. Townsend, G. H. Washburn and A. Worcester; the guests, Drs. R. T. Edes, E. A. Bates and H. A. Wood, to all of whom I am much indebted.

Combining the two sets of statistics, the frequency of the three classes in the 159 cases is in the proportion of 53, 24 and 23 per cent., in the order given above; and the mortality is 34 per cent. in the ante-partum, 21 per cent. in the inter-partum, and 22 per cent. in the post-partum cases. As in the hospital, a large number that were comatose recovered, 41 per cent. proving fatal.

The correspondence in the average number of convulsions in those who recovered and those who died is almost exact. Thus, in private practice the average number of convulsions which ranged from 1 to 18 in those that recovered, was 4.1 against 5 in the hospital. In those that died, the range was from 1 to 20, and the average 8.2, — exactly the same as at the hospital.

As in the hospital cases, there seems to be no relation between the number of the convulsions and the condition of the child at birth, whether living or not. Thus, the average number of ante- and inter-partum convulsions where a living child was obtained was 3.2, the average number where the child was still-born being about the same, namely, 3.6. There were three children born dead where the mothers had each had only two convulsions, the cause of the death being probably the forced delivery, while one child survived nine maternal convulsions.

Dr. R. T. Edes reports three labors of one patient, twice at the sixth month and once at the seventh, in all of which there was eclampsia — from five to twelve ante-partum convulsions, forced labors, and two to six post-partum convulsions. The patient has had a healthy living child born since, without eclampsia. He also reports two other eclamptic labors in another patient, the patient dying in the last one.

Dr. C. E. Stedman reports two eclamptic labors in the same patient, who survived.

The treatment in the private cases collected, judging from the notes sent me, has been in the main essentially the same as the hospital treatment, namely, early delivery and the use of an anesthetic, hot-air baths, purgatives, diuretics and in some cases pilocarpine. The use of chloroform instead of ether is mentioned in only two or three cases.

Dr. J. P. Reynolds reports cases where ether to complete anesthesia was pushed for a long period. His results are certainly remarkable; for, out of twelve cases reported, only two died, and in both of these ether was not thoroughly given. I cannot help feeling, however, that he was particularly fortunate in these results, for series of eclamptic cases have occurred at the hospital where everything seemed powerless to prevent a fatal issue.

Theoretically, I cannot understand why the suppression of the convulsions by ether is going to cure the disease any more than the suppression of the cough in pneumonia would stop the progress of this affection. Both the convulsion and the cough are merely symptoms of an underlying condition. It also seems to me that ether by increasing the pulmonary congestion and cyanosis is helping rather than retarding the effect of the toxins towards a fatal issue. Certainly many of the fatal cases show in the last stages cyanosis and bronchial accumulation which can only be aggravated by ether. Chloroform seems the more rational agent to use.

Pilocarpine, it seems to me, by increasing the danger of bronchial accumulation should not be used in eclampsia.

The use of morphine is mentioned in nine cases by various reporters, two of these cases proving fatal.

Eight cases were bled, three proving fatal. One of these latter was a case of my own, where the patient was promptly delivered, but where the convulsions continued for two days post-partum until her death, notwithstanding every means that could be employed. Here venesection gave temporary relief. Copious bleeding, followed by intravenous salt-solution injections, would seem to promise good results.

The use of *veratrum viride*, as recommended by many practitioners in the South and West, is not mentioned in this collection of cases.

Clinical Department.

A CASE OF BULLET-WOUND OF THE HEAD.

BY A. T. CABOT, A.M. M.D., BOSTON.

C. H., fifty-five years of age, entered the Massachusetts General Hospital on October 25, 1892. Twenty hours before entrance he had shot himself in the left side of the head with a revolver, the bullet, of 32-calibre, entering just above the left temporal bone. He was a Swede, and talked but little English, but would answer "Yes" or "No" to simple questions.

An examination showed the characteristic wound of entrance of a bullet of the described size. This opening was situated one and a half inches above a line drawn from the external orbital process to the junction of the helix of the ear to the scalp, and was nearly over the centre of this line, being slightly nearer to the ear than to the orbital process. His eyes were moderately contracted, but reacted equally to light. At the time of entrance his temperature was 101.4°; his pulse was 90, his respiration 36. He was seen soon after by Dr. J. J. Putnam, who made the following notes:

"The patient shows complete paralysis of the lower branches of the facial nerve, and difficulty in the movements of the tongue, also complete paralysis of the right hand and arm. Neither leg is wholly paralyzed, but both are equally weak. The knee-jerk is slight, but present at both sides. He is sensible to a prick everywhere. He seems to understand simple questions, and is apparently intelligent, but is evidently aphasic. His pulse is 84, respirations 27. He can swallow."

Dr. Putnam's opinion was that the lower Rolandic region, which lay close to the wound, was evidently seriously injured. How much further the damage extended could not be determined on account of the condition of general concussion. It was decided to operate with the object, primarily, of establishing drainage.

After thoroughly shaving and cleansing the head, the scalp was reflected and a trephine opening was made over the point of entrance of the bullet. A probe was then introduced through the opening in the dura mater, and, with the head turned on the side, was allowed to run by its own weight along the track of the ball. It slipped along easily until it encountered the falx, where it stopped abruptly, but a little gentle manipulation carried it through the opening and it then ran, by its own weight, directly across to the skull on the other side. By taking a probe long

enough to project considerably from the skull, while it lay in the bullet track, it was possible to sight pretty accurately the course of the ball. It was thus found that it had traversed the brain from side to side with an inclination backward; so that it must have struck the inside of the skull, on the other side, under the posterior part of the parietal eminence.

The probable point being determined by careful observation of the probe, a needle was thrust through the scalp, and, reflecting a flap, a trephine was put on; and when the button of the bone was removed, it was found that the probe from the other side touched the dura at the centre of the opening.

An incision was made in the dura, which had not been lacerated by the bullet. At once clots of blood and brain matter began to issue, and a probe, feeling about with great gentleness, demonstrated a cavity in the brain substance posterior to the opening. The finger was carefully introduced into this; the bullet was felt and, with a little difficulty, was seized and removed.

A drainage-tube was introduced into the cavity where the bullet had lain, and another small one was slipped just within the wound of entrance.

The patient gradually failed, and died twenty-four hours after the operation.

The interesting point in this case is that the method adopted succeeded in so accurately locating the point of the probe on the opposite side of the head. The probe was sighted while looking at the head first from the top and then from the side, and in each position a line was drawn passing around the head in the same plane with the probe and the eye. The point of intersection of these lines on the opposite side gave the position of the distal end of the probe. Fortunately, the bullet had not ricocheted after striking the inner surface of the skull, and was found close to the point of impact.

Patients often recover with an injury of the brain as extensive as seemed to exist in this case; and it would seem possible that had this patient come to operation earlier, the result might have been more favorable.

A BULLET-WOUND OF THE BRAIN.

BY DAVID DANA SPEAR, A.M., M.D., FREEPORT, ME.

ON December 30, 1896, a little child, twenty-one months old, was accidentally shot with a bullet from a .22-inch calibre revolver. The missile entered the head on the posterior left side about midway between the upper part of the left ear and the occipital protuberance. The direction of the line of entrance was diagonal. There was no wound of exit. Matted hair, looped, two and one-half inches in length, was taken from the wound; so that it must have been of at least that depth, and how much more is unknown. The wound was not probed.

Immediately after the shot the child fell to the floor, apparently dead; but after a few moments began to breathe irregularly. An hour later she was seen by the writer. The condition was one of severe shock and concussion; both pupils were contracted to a small point and were inclined to roll upward.

Two hours later she was seen by Dr. Twitchell, of Portland, who concurred that the wound should not be probed to find the bullet. The condition of concus-

sion lasted about five days, when consciousness gradually returned, and at the present writing the child is apparently as well as at any time in her short life. There is no paralysis, no change of vision, no fever; since the fifth day of the accident, no vomiting.

The treatment of the wound was antiseptic until healing had taken place. The bullet is still in the brain, and gives no symptoms.

Reports of Societies.

THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

REGULAR Meeting December 15, 1896, the President, DR. JAMES R. CHADWICK, in the chair.

DR. ALFRED WORCESTER reported

FIVE CASES OF ECLAMPSIA, WITH COMMENTS UPON THE TREATMENT.¹

DR. CHARLES W. TOWNSEND read a paper on

PUERPERAL ECLAMPSIA,²

which was a study of 160 cases occurring at the Boston Lying-in Hospital and in the private practice of members of the Obstetrical Society of Boston.

DR. A. D. SINCLAIR said he could not agree with Dr. Worcester that manual dilatation and version was poor treatment in eclampsia. It is of great importance to fully dilate the cervix before attempting to extract. Cases of eclampsia differ very much in severity; some will get well, and some will die in spite of treatment, but he knew of no one remedy so successful as manual dilatation and version.

DR. J. P. REYNOLDS had never seen any harm from the prolonged and continuous use of ether, neither had he seen any recurrence of the convulsions after its persistent use.

DR. F. B. HARRINGTON remarked that the diminished urine in these cases was probably a symptom of the general toxemia, and not a cause.

DR. J. G. BLAKE said that his own course of action was to give ether and empty the uterus at once, and that he relied on the record of five successful cases to bear him out in this belief. In two others that had come under his observation where other methods were first used the patients were lost.

DR. GEORGE HAVEN said the whole subject was shrouded in mystery, and there is much yet to be learned about the pathology and proper treatment of the affection. On theoretical grounds he would prefer chloroform to ether in these cases, although he had not used it. In some cases hot-air baths will not produce sweating and pilocarpine will.

DR. DOLLIVER stated that Tarnier had reduced the mortality from eclampsia in recent years in his clinic to nine per cent. by means of a milk diet.

DR. ENGELMANN believed if we bleed we must do so freely, and if we use morphine we must give large doses. He had always used chloroform, never having used ether or pilocarpine. He had placed some reliance on calomel. He believed in delivery as soon as possible, in venesection and in large initial doses of morphine. He believes that the ideal treatment would

be venesection with intra-venous injections of salt solution, thus ridding the system of toxins. He referred to a recent report of 31 cases in Geneva, four of which had icterus of which three died, showing that the liver as well as the kidneys is affected by the toxemia.

DR. J. B. SWIFT said he would like to ask what constituted the rationale of immediate delivery. If the child has not reached a viable age, why sacrifice it? It would seem as if we should devote ourselves to the elimination of the poison.

DR. A. D. SINCLAIR said that early statistics give a mortality of 50 per cent. in eclampsia. It is about one-half that now, the improvement being due, he thought, to anesthesia, rapid delivery and the use of prophylactic treatment.

DR. C. M. GREEN said he had seen a large number of cases at the Boston Lying-in Hospital and in consultation practice, but had never had a case in his own practice, although he has, he thinks, prevented a number by prophylactic measures. The most important thing in the examination of the urine is the amount of urea, not of albumin. He has recently had a case where there were headaches, epigastric pain, edema and albuminuria, but under prophylactic treatment no eclampsia resulted. The pathology of the affection is still obscure. In one autopsy made by Dr. Councilman there was found to be general pneumococcus infection of the liver, lungs and all the organs.

He believes in the delivery of the eclamptic patient, experience showing that that gives the best results. He referred to a case where marked edema occurred in the latter part of pregnancy. In spite of most careful prophylactic treatment the patient had convulsions. She was at once delivered, and had no more; and a year later her urine was normal. He does not look on pilocarpine as such a dangerous drug as some think, and he uses it where hot baths do not work. Hot-water baths are excellent, being far better than the hot-air baths for inducing perspiration, but they are more difficult to manage. The patient should be kept in the bath till the forehead is covered with perspiration.

DR. W. E. BOARDMAN said that manual dilatation and delivery was used in the earlier part of the century by Ashwell and Michael Regan. It was given up, but we have again returned to it.

DR. A. WORCESTER said that in eclampsia the common practice is to absolutely disregard the life of the child. He would urgently recommend the practice of prophylactic treatment in all cases indicating approaching eclampsia, and of all symptoms the diminution or suspension of urine is most important. He believes that ether does no good; he has lost four cases where full etherization was employed.

DR. C. W. TOWNSEND, in closing, referred to the great variation as to mortality in cases of eclampsia. Some of those that are apparently most hopeless recover, while others that are seen early and appear to be most promising, die. He read the following reports of post-mortem examinations recently made by Dr. J. H. Wright on cases of eclampsia dying at the hospital.

Synopsis of Autopsy upon H. K.—Body that of a young well-developed woman, showing evidence of recent pregnancy. The chief lesions were as follows:

Liver. Pale, yellowish, opaque, showed some punctate hemorrhages in capsule. The microscopic examination

¹ See page 204 of the Journal.

² See page 205 of the Journal.

showed minute foci of necrosis of the liver cells and invasions of leucocytes, also some fatty degeneration.

In the Endocardium a patch of punctate hemorrhage and some fatty degeneration in heart muscle.

Kidneys. These showed a narrow cortex and considerable evidence of degeneration. The microscope showed the chief lesions to be acute in character. The vessels of glomeruli showed a special hyaline degeneration with a thickening and obstruction of calibre. The secreting tubules showed marked acute degenerative changes.

In the Lungs microscopic examination showed blood plate thrombosis of numerous small vessels and a few multinucleated cells in the capillaries of the alveolar walls. These cells are probably of placental origin.

Spleen. Not remarkable to the naked eye; microscopic examination, however, showed foci of degeneration and necrosis in the malpighian bodies, similar to those seen in diphtheria in this location.

Bacteriological examination failed to show any definite bacteriological infection.

Synopsis of Autopsy on A. B.—The body was that of a young woman well developed and nourished, showing the usual evidences of the puerperal state. The most striking lesions to the naked eye were as follows:

Liver. Soft and generally putty-like in color and appearance. Its capsule showed numerous punctate hemorrhages and reddened discolorations. The organ was not especially diminished in size. In section, scattered throughout the tissues were seen groups of pale, slightly reddish, ill-defined areas, probably foci of necrosis with more or less hemorrhage.

On the Endocardium, and in the Pleura there were marked punctate hemorrhages.

In the posterior portion of the Lungs there were small circumscribed areas, dark red in color, probably hemorrhagic in character.

The Kidney showed very marked degenerative changes of acute character, but no evidence of long-standing disease.

The Uterus was not especially remarkable.

The Spleen was not enlarged, but showed numerous dark-red points and spots in its pulp.

Brain normal.

Bacteriological examination failed to show any definite infection.

NEW YORK NEUROLOGICAL SOCIETY.

STATED Meeting, February 2, 1897, the President, BERNARD SACHS, M.D., in the chair.

CASE SIMULATING SYRINGOMYELIA.

DR. GRAEME M. HAMMOND presented a lady who, ten years ago, after an illness similar to an attack of *la grippe*, began to have loss of sensation to pain and temperature in the left arm. During these ten years the symptoms had extended to the left leg, trunk and side of the face. Dr. Hun had carefully examined her, and had made a diagnosis of syringomyelia. When first seen by the speaker the symptoms had been certainly very like those of that disease—absolute insensibility to temperature and pain, with perfect preservation of the sense of touch. But the absence of paralysis and contractures, the normal electrical contractility, and the fact that the other side was not affected argued against this diagnosis. In addition to this, there were several symptoms of neurasthenia—insomnia, noises in the ears and confusion of ideas. It had occurred to him that the case might be of neurasthenic origin, and acting upon this theory she had been given bromides, together with as much mental impression as possible. The result had not been dis-

appointing. Now, the pain and temperature sense had returned in the face and trunk. The sensation of pain and temperature were not fully restored in the left hand or in the trunk, but were decidedly improved. She had never been told what the symptoms of the disease were, so that there could have been no suggestion.

DR. M. ALLEN STARR suggested that there might possibly be a small area in the cord of disease that had started the symptoms and given the "suggestion," thus making the case a complex one.

CEREBELLAR ATAXIA.

DR. GEORGE W. JACOBY presented a little girl of nine years, a typical case of cerebellar ataxia. In this case there was no heredity. The father married his own niece, but with this exception the family history was negative. This child did not walk until three years of age, and was generally backward, both mentally and physically. Examination showed marked ataxia in both upper and lower extremities. When unobserved, the child exhibited constant choreiform movements of the head and upper extremity. When walking, the body was thrown forward and the head somewhat backward; the legs were spread far apart and there was a constant tendency to falling. In reaching for an object, there was an uncertainty of movement. The eyes showed a slight fixation nystagmus at times. There were no changes in the optic nerve. The reflexes were very much exaggerated. There was no deformity in the lower extremities. He felt that the case should be looked upon as a congenital defect of the cerebellum.

DR. JOSEPH COLLINS endorsed the last statement of Dr. Jacoby. He had looked into the literature of the subject, and had been impressed with the necessity of differentiating between hereditary and familiar changes. In a case that he had had there had been no hereditary history whatever, nevertheless, a younger child, who had died about the end of the second year, and was described as having had from its birth "St. Vitus' dance" and other symptoms, had probably suffered from the same disease.

DEMONIACAL POSSESSION.

PROF. WILLIAM JAMES, of Harvard University, delivered an address on this subject. He said that our knowledge of altered personality had made rapid strides in recent years. We had the transient altered personality of epileptic insanity, and certain dream states that had been described under the name of "ambulatory automatism"—the subject going from home and returning after an interval of, perhaps, weeks, with the memory of what had happened during his wanderings utterly effaced. In one case that he had treated, hypnotic suggestion had brought back the memory of the wanderings. There was still another altered personality, that called "spirit control." This was connected with demoniacal possession. The obsolescence of public belief in the possession by demons was a very strange thing in Christian lands, when one considered that the sacred books of our religion were full of this belief. Every land and every age had exhibited the facts on which this belief was founded. The particular form of supernatural origin varied with the traditions and popular beliefs of each country. When the Pagan gods became demons, after the triumph of Christianity in Europe, all possession was

looked upon as diabolic. It was now replaced by the thoroughly optimistic belief that changed personality is the spirit of a human being coming to bring messages of comfort from the sunny land. The unconsciousness, the speaker said, was usually ushered in by a more or less pronounced convulsion—the person's character became entirely changed in its attitude, voice and manifestations. After an hour or two, the manifestation passed off, leaving a complete amnesia behind of everything that had occurred. During the intervals of the attacks the person was entirely well. The condition was, therefore, entirely distinct from any form of insane delusion. Mr. Percival Lowell had reported that in Tokio, Japan, there were a number of persons who cultivated the power of passing into trances. In China, there was a widespread belief that possession by gods and spirits could take place. Mr. Nevins, a missionary in China, had reported a number of cases of demoniacal possession. In Japan there was a curious superstition that the person afflicted was not affected by a demon but by a fox. In India, instances of this kind were extremely common.

The speaker said that the witchcraft delusion had been explained in various ways, but to him witches were not neuropathic persons, but the accusers were. He had carefully examined the witchcraft trials, and had found that it started in some demon disease in the neighborhood. These "demon diseases" were very common in those days, being any functional neuropathic disease. If there were no obvious physical disorder, and the symptoms did not yield readily to the usual medical treatment, the case was considered to be one of demon disease. Professor James quoted from a book written in 1803, by a French magistrate, in which a detailed description was given of a girl possessed of five demons, and the manner in which they came out of her mouth, and ran around the fire two or three times before disappearing. He said that these descriptions reminded one of the classical hysterical attack—the lump in the throat, the convulsive seizures, etc. The cases appeared to be examples of imitative hysteria, patterned after the cases existing at that time. Differences in the different countries, of course, came from the differences in the psychological climate. Many interesting reports had been published of late years of epidemics of chorea, supposed to have resulted from imitation. These epidemics had been known to last for months or even years. An interesting case of demoniacal possession in France in 1863, had been reported by Dr. Augustine Constance, in Savoy. A similar epidemic had been reported in Italy. The epidemic in France began with hysteria among certain children, and was propagated by example until at last a very large number of persons was attacked with all the symptoms of demoniacal possession. When Dr. Constance arrived upon the scene, a year after the breaking out of the epidemic, 110 persons were affected. He examined a number of these individuals, and found them to be suffering from hysterical attacks, brought on by suggestion. The patients were wisely sent away to other villages, and in that way he broke up the epidemic. Hystero-demonopathy is the name given to these symptoms.

No one could fail to recognize in these attacks the analogy to the performances of the numerous spiritualistic mediums of the present time. It would be strange indeed, if a phenomenon which had played such a large part in history should have died out without leaving

anything in its place. Medical men should learn from all this a certain lesson, that is, that as our views had become optimistic instead of pessimistic, the whole thing had become harmless. We live in a day when there is much alarmist writing in psychopathy about degeneration, and the alarming significance of all sorts of symptoms and signs, so that there is danger of drawing the line of health too narrowly.

DR. C. A. HERTER said that the idea of connecting the powers of modern spiritualistic medium with the peculiar forms of demoniacal possession which occurred in former years was a most interesting one. This fact had been brought out most interestingly and impressively in the address. He had been much interested in the gradual change from the damaging to the comparatively beneficent aspect of these phenomena.

MR. MARTIN said that it seemed to him rather remarkable that the suggestions which occurred to the possessed person, related almost entirely to ethical matters or religious subjects. A large portion of the recorded cases that he had met with referred to the possession by devils, who were leading the person astray or into immorality. He would like to ask if Professor James had observed the same thing.

PROFESSOR JAMES replied that it was a law of the secondary consciousness that it took the religious form. He had no explanation to offer, however, of this law. It was a singular fact that involuntary writing was apt to take the spiritualistic form. This would occur in the case of persons who had no intellectual hospitality for that view, and who had not been exposed to spiritualistic influences. Spirits, religious truths and philosophical discourses were the staple of these communications.

DR. MARY PUTNAM JACOBI said that, as in so many cases of melancholia the grief was about having sinned against the Holy Ghost, even in persons who had had no religious or Calvinistic instruction, she would like to ask if Professor James considered it an example of the phenomena just spoken of. She would also like to ask his opinion of an essay that had been published, entitled, "Were the Salem Witches entirely Guiltless?" According to this essay, although these witches were not possessed by devils, they were abandoning themselves to impulses coming from the lower structures of their natures—the result of ancestral influences.

PROFESSOR JAMES replied that he did not think the delusions of melancholia had anything to do with the subject under discussion. The sin against the Holy Ghost was only an endeavor to explain the grief which was felt. Regarding the essay by Prof. Barrett Wendell, to which allusion has been made, he would say that at the time of the witchcraft belief there were certainly persons attempting to do what they could by diabolical aid, but in all probability they formed a very small part of it. In Salem, the girls from whom the accusations emanated had been having hypnotic seances from a West Indian slave, who was herself practically insane. They passed then into such a condition that they were accused of witchcraft, and were tried under such circumstances as to impress them powerfully by suggestion. From what we know of imitative hysteria, the whole matter was entirely explicable on that basis, without any supposition of guilt upon the part of these children. It was a suggestive epidemic of a semi-hysterical nervous disorder.

DR. C. L. DANA said that the speaker had made

quite clear the relation of trance to demoniacal possession of old, but he would like to know how widespread was this condition now. He knew that about fifteen years ago spiritualism had been immensely prevalent in the Eastern States. If the condition had continued to exist and spread, there was certainly much more in the United States to-day than in civilized countries several hundred years ago.

PROFESSOR JAMES replied that it would be difficult to answer this question statistically, as we had no trustworthy statistics. We knew, however, that at the present time there were many "faith-healers."

Recent Literature.

Text-Book of General Pathology and Pathological Anatomy. By RICHARD THOMA, Professor of General Pathology and Pathological Anatomy in the University of Dorpat. Translated by ALEXANDER BRUCE, M.A., M.D. Vol. I, with 436 illustrations. London: Adam & Charles Black. 1896.

We are glad to note this translation of the "Lehrbuch" of this well-known teacher of pathology.

The book is especially valuable for its presentation of the subject of "Disturbances of the Circulation of the Blood," a subject about which the author is well qualified to write by reason of his important contributions to this department of pathology.

The portions of the book dealing with bacteria, parasites and the general subject of etiology do not call for special commendation, while the chapter on fever is unsatisfactory. The consideration of tumors is good; their histology is well illustrated by wood-cuts.

The work is of interest as containing a presentation of the author's somewhat peculiar ideas on the subject of inflammation, and his reasons for advocating the abandonment of the use of the term in pathology.

The part of the publisher has been well performed, and the volume is a most attractive one.

A Text-Book of Special Pathological Anatomy. By ERNEST ZIEGLER. Translated and edited from the eighth German edition, by DONALD MACALISTER, M.A., M.D., and HENRY W. CATTELL, M.A., M.D. Sections I-VIII. New York: The Macmillan Co. 1896.

This translation of the latest German edition of the "Specielle Pathologie" of Ziegler will be welcomed by medical students who cannot read German fluently. The many merits of the German original and its great usefulness as a help in the study of pathological histology are well known.

All the wood-cuts of the original are fairly well reproduced, and the book is excellently printed and bound.

The Pathology of the Contracted Granular Kidney and the Associated Cardio-arterial Changes. By SIR GEORGE JOHNSON, M.D. (Lond.), F.R.C.P., F.R.S. With 29 illustrations. Philadelphia: P. Blakiston, Son & Co. 1896.

This little book represents the results of the author's studies in the pathology of interstitial nephritis carried on about thirty years ago. It has considerable historical interest, but it is not to be regarded as an adequate presentation of the present state of our knowledge of the subject with which it deals.

A Text-Book of Diseases of the Nose and Throat. By FRANCKE HUNTINGTON BOSWORTH, A.M., M.D. With nearly 200 engravings, and seven full-page chromo-lithographic plates. New York: William Wood & Co. 1896.

This book is made by condensing into one volume the author's well-known work on the Nose and Throat. The condensation has been admirably done, and gives us the best English text-book on the subject for the use of the medical student and general practitioner. As in the unabridged edition, the arrangement of subjects is excellent, and the description clear and interesting. The choice of methods of treatment must always be a difficult one for a text-book. It might, for instance, be questioned whether the author's free use of cocaine would find favor with other teachers of the art. The most obvious criticism of the book as a whole would be that the reduction had not gone far enough. With the larger work on which to fall back more might have been omitted. Seventy pages are devoted to the external surgery of the nose and throat, subjects which would hardly be looked for in an abridged students' manual. Nevertheless the book is not unwieldy, and we are spared the descriptions of individual cases and unimportant discussion.

Autoscopy of the Larynx and the Trachea. (Direct Examination without Mirror.) By ALFRED KIRSTEIN, M.D., Berlin. Authorized Translation (altered, enlarged and revised by the author) by MAX THORNER, A.M., M.D., Cincinnati, O. 68 pages. Philadelphia: The F. A. Davis Co. 1897.

This is a description of the technique by which the larynx and trachea may be examined and treated directly, without the necessity of reflected images. The principle lies simply in getting the tongue downwards and forward, so that a straight path is opened, a continuation upwards of the line of the tracheal volume. The autoscope consists of a straight grooved spatula, the tip of which is inserted in the groove between the tongue and epiglottis. The author does not claim that the laryngoscopic mirror is to be superseded, but that this is a valuable addition to our present methods of examination and operation, especially for the posterior wall of the larynx and the trachea. On account of individual differences in patients, it is not universally applicable, and its proper manipulation can come only with practice and skill on the part of the operator. It is, of course, too soon to predict its future.

Functional Disorders of the Nervous System in Women. By T. J. MCGILLICUDDY, A.M., M.D. 8vo, pp. vi, 334. With 34 illustrations, 12 charts and 2 chromo-lithographic plates. New York: Wm. Wood & Co. 1896.

This is one of the books which are manufactured by the aid of the shears and the mucilage-bottle, and contains pages of quotations from familiar sources. The pages not in quotation marks are characterized chiefly by a remarkable lack of knowledge of nervous disorders. Although leading neurologists now look with scepticism upon the so-called reflex origin of certain nervous disorders, the author ascribes to reflex irritation the bulk of nervous affections occurring in women; but his consideration of the subject is unsystematic, his study of cases is superficial, and the book is full of statements that are rarely accepted at the present day.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MARCH 4, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,

NURSES AND NURSES.

THERE has recently appeared in the *Nineteenth Century* an article by Lady Priestley in which the shortcomings of the English trained nurse, or nurse *à la mode* as she is there styled, are vividly portrayed. She is described as too often conceited in her pseudo-scientific "training"; not seldom unwilling to perform the more menial offices of the sick-room; as frequently usurping the functions of the doctor, regulating the diet and treatment of the patient herself; as sometimes frivolous, flippant and flirtatious. She frequently regards herself as above her station and makes herself a nuisance in the houses of people of moderate means, by constantly impressing this fact upon the patient and the family. She has been known to make use of the exceptional opportunities offered her in her personal relations to eligible single gentlemen to entangle them in matrimonial alliances, and if unsuccessful, to sue them for breach of promise, and to mulct them in considerable sums of money. In fact, if the possibilities depicted by Lady Priestley were to be accepted, physicians and patients would prefer to take their chances with any ignorant, untrained, but obedient and kind-hearted woman, who would carry out the doctor's orders in a faithful though clumsy and slipshod manner, to the ministrations of one of the class of trained nurses which she describes.

A reply to this article, by Mrs. Bedford Fenwick, formerly matron of St. Bartholomew's Hospital, in the February number of the same periodical, points out the fact that Lady Priestley has done trained nurses as a class the greatest injustice in attributing to a considerable number of them qualities which are only shown by a very small proportion of the graduates of training-schools, and these few the black sheep of the flock, some of them perhaps sailing under false colors by the aid of forged or stolen certificates.

There can be no question that a certain number of the nurses who graduate from training-schools lack

the tact, kindness of heart, and love of their work to fit them for the successful practice of their profession; but there can also be no question but that a woman who possesses these necessary qualifications is an infinitely better nurse for having gone through the ordeal and experience of a training-school. Without the peculiar qualities of mind and heart and the bodily strength essential to her calling, no amount of training will make a woman a good and useful nurse, but when to these instinctive qualities are added the knowledge of symptoms, the power of dealing with emergencies, the mature judgment, and the mastery of the countless practical details of the care of the sick which the training-schools of our own large hospitals afford, then only does a nurse become fitted for the care of serious cases.

For the seriously sick and even for invalids or for the weary, who can afford the expense, there is no greater comfort next to a skilful, cheerful, sympathetic doctor, than a good, cheerful, tidy, sympathetic trained nurse, and we are glad to bear testimony to the very valuable services rendered to individuals and to families by very many such in our own country. The fees which such nurses command are doubtless too high for many patients of moderate means; but when we take into consideration the arduous nature of the duties, the intervals of rest which a nurse is forced to take in order to keep her health, and the shortness of the active wage-earning period of a nurse's life, they seem none too large.

Nevertheless, the problem of providing good nurses for people of moderate means is a serious one, and we are glad to learn that at the last meeting of the superintendents of training-schools for nurses, held recently in Baltimore, the subject of "visiting nurses" was under discussion. The visiting nurse is ready to be summoned to attend during a confinement, or surgical operation perhaps, leaving the house as soon as the patient is properly cared for, and then visiting the patient once or twice a day for dressing, bathing or such other care as the patient may need. The system has had excellent results, it is reported, in several cities of this country, and is just being introduced in Boston. The advantages of such a system to self-respecting families of moderate means are obvious.

But there are certain other advantages which will accrue under such a system to the nurse herself. She will not, in the first place, be frequently subjected to the wearing monotony of the care for weeks or months of a nervous and often selfish invalid. She will have a constant variety of cases, often serious, instructive and interesting, and will in going from house to house gain the often much needed benefit of air and exercise.

Such a system will resemble in many respects that which is provided already in our city for the very poor by the Instructive District-Nursing Association. Let those who cavil at trained nurses and their work look at the record of a year's work of these eleven trained nurses in our note on page 216 of this issue.

Or, better, let them follow one of these devoted women on their daily errands of mercy. Let them see these nurses, trained in the best of our modern schools, go into the slums of our city, through the dark alleys, among the ash-barrels and swill, up the dark, dirty, rickety staircases of the tenements, and into houses of poverty and filth, unshrinking in their devotion to their duty. See them go there, and minister to the sick and serious cases in these often loathsome surroundings. See them bring with them clean linen from the stores of the Association, teach these ignorant families the value of cleanliness and ventilation, make the patients as clean and comfortable as is possible under the conditions, and coax them back to health. The change which will come over a household after a few of these visits is wonderful. The district physician who works with the nurse can best appreciate it. The poor, ignorant families, who have never before learned the value and comfort of cleanliness, learn it from these nurses, and bless them ever after for having taught it.

These nurses are not paid twenty-one dollars a week; but if ever consciousness of having done great good under the hardest and most repulsive conditions is any reward, that reward is theirs.

The difference between Lady Priestley's trained nurses and the type of nurse we have described is great enough. One is the personification of selfishness, and the other of unselfish devotion to duty. The larger class perhaps will lie between the two extremes; but let us beware of taking as a type the worst examples of the worst class.

SERUM-THERAPY IN SYPHILIS.

THE serum treatment of syphilis has been employed hitherto in the three following ways: (1) Injection of the serum of healthy animals—dogs (Richet, Héricourt, Fenlard), sheep and calves (Tomassoli, Kollmann, Mozza, Istomanow). (2) Injection of human serum from patients in the secondary and gumous stages (Pellizzari, Wjewiorowski) and from children with hereditary syphilis (Bonaduce). (3) Injections with serum from animals which had been previously inoculated with syphilis by means of (a) injections of the serum of patients with primary syphilis, or at the acme of secondary manifestations; (b) inoculation of primary syphilitic ulcers, and moist papules, as well as injection of serum of patients with the full development of secondary manifestations. No positive good results have thus far been proved to have followed the serum-therapy.¹

Nevertheless, the great success of the serum-therapy in diphtheria, and the attempts to produce a serum for the cure of erysipelas, pneumonia, cholera, etc., have encouraged students to continue their investigations of a serum-therapy for syphilis. It has been shown in the case of diphtheria, that the blood serum

of animals which possess a natural immunity from diphtheria, has no therapeutic effect. In order to obtain an anti-diphtheritic serum, it is necessary that the animals be in a certain measure receptive for the inoculation. Tarnowsky believes that horses are more or less receptive to syphilis, as in some foals inoculated by him with syphilitic products, nodular interstitial lesions were found in the liver, spleen, kidneys and lymph glands, which showed microscopically a great similarity to those of syphilis. If, therefore, these animals are in some degree receptive to syphilis a serum obtained from them when rendered immune by repeated inoculations, would be completely analogous to anti-diphtheritic serum.

On this assumption three young horses were treated by successive inoculations with the products of syphilis, and the serum obtained from their blood was injected experimentally into six syphilitics who had had no previous treatment. The result of these experiments showed that the injection of serum from syphilized horses had no favorable influence on the course of syphilis, not only in the earlier but also in the later stages of the disease, and that it was not to be recommended as a method of treatment. It was found, moreover, that the injections exercised an unfavorable influence on the general condition of the patients, causing a rise in temperature, albuminuria, outbreaks of purpura, and a loss of weight.

The question of serum-therapy as a cure for syphilis may, however, be approached from a different standpoint. In case, as was conjectured by Behring, the efficacy of autitoxin consists, not in a destruction or neutralization of the toxins, but in an increase of the capacity of the system for resistance, it is conceivable that in the treatment of syphilis by mercurials, we do not directly disinfect the system, but increase its power of resistance. On this supposition it is possible that the serum of animals which are in some measure susceptible to syphilis, and whose immunity has been increased by saturation with mercury, may be effective in the treatment of syphilis in man. Experiments on these lines have been already undertaken by Tarnowsky.

In 1891 Boeck² treated a dozen cases of recent, so-called secondary syphilis by means of injections of syphilitic serum obtained from the fluid of a hydrocele, in a syphilitic subject in the secondary stage. The results were not very striking. Of four patients treated in private practice only one had a slight recurrence of syphilitic symptoms. No news was obtained of the hospital patients.

During the last year somewhat similar experiments were made on seven patients from private practice. The serum was taken from a man who had acquired syphilis six years before and was then suffering from epididymitis and hydrocele. In the first six cases the treatment was begun before the outbreak of secondary symptoms, in the last case after the appearance of the exanthem. The injections were made into the skin of

Archiv. f. Derm. u. Syph., 1896.

² Archiv. f. Derm. u. Syph., 1896.

the back. The results of these experiments were that the primary symptoms disappeared more quickly under serum injections than under expectant treatment. Sometimes the effect was quite striking. The glandular affection of the primary period was also influenced. When the injections were made before the appearance of secondary lesions, the latter were delayed and attenuated, so that the exanthemata were barely visible, and there were few appearances on the mucous membranes. Boeck found that the injections were more effective the earlier they were begun, and that this tertiary serum was far more effective than that of the secondary period. He is forced to admit, however, that the serum injections do not have nearly so quick and decisive an effect on the symptoms of the early period as the ordinary specifics, mercury and iodine. In six cases of those treated by the injection of serum the secondary period lasted on an average four months and twelve days, and all secondary manifestations had disappeared on an average six months and three weeks after the date of infection. These cases were followed for many months; and Boeck is satisfied that the secondary period was surely at an end. The question now arises, How does this result compare with that attained by ordinary specific treatment? Do not secondary appearances last longer on the average, under the latter method?

MEDICAL NOTES.

MEDICAL AND TECHNICAL EDUCATION IN MADAGASCAR.—A medical school is being organized in Madagascar, and a native technical school has already been opened.

DR. CERNA RECEIVES A CONSULAR APPOINTMENT.—Dr. David Cerna informs us that he has been appointed by the Mexican Government, to the Mexican Consulate at Galveston, Texas.

THE GERMAN CONGRESS OF SCIENTISTS AND PHYSICIANS.—The sixty-ninth Congress of the German Association of Scientists and Physicians will be held this year at Brunswick from September 19th to 25th. The work is distributed among thirty-three sections.

DR. DACOSTA APPOINTED TO A PROFESSORSHIP.—The Board of Trustees of the Jefferson Medical College, Philadelphia, recently appointed Dr. J. Chalmers DaCosta, Clinical Professor of Surgery. Dr. DaCosta has been connected with the Jefferson School for many years, and has recently been Demonstrator of Surgery and Chief of the Surgical Out-patient Department.

CASTRATION FOR RAPE.—The house committee on public health of the Kansas Legislature has made a favorable report on a bill which does away with a penitentiary sentence for men convicted of assaulting women, and substitutes castration. The Social Purity League of Topeka has been urging the passage of this bill, and the leaders in the league claim enough votes in both houses to pass the law, and have secured the

promise of Governor Leedy's signature. They say that, following the lead of Kansas, ten other States will pass the same law at the next session of their legislatures.—*Medical Record.*

A DEATH AT THE AGE OF ONE HUNDRED AND TWENTY-THREE.—Mrs. Caroline Woods is reported to have died in St. Louis, Mo., recently, aged one hundred and twenty-three. She was almost the first white child born on the present site of Louisville, Ky., where she was married in 1800. Mrs. Woods had a remarkable memory, and related many incidents of life on the frontier.

PERSONAL CLEANLINESS IN ARCTIC EXPEDITIONS.—At a dinner given in his honor by the Savage Club in London, Dr. Nansen spoke of the great difficulties encountered by his expedition in maintaining personal cleanliness. "We did our best to keep ourselves clean," he said, "and tried all sorts of different ways. We tried the Esquimaux way, but that was no good. What we had to do was to use the knife and scrape ourselves. The Esquimaux method is that of preserving all the urine secreted by the members of the establishment, and using it for all purposes of domestic and personal cleanliness."

THE MEDICAL SCHOOL OF NEW YORK UNIVERSITY.—The trustees of the New York University have accepted the deed of the Loomis Laboratory, and at the same time the Medical School, which, since its establishment in 1841 has been under the management of a separate board of trustees, now passes under the control of the trustees of the University, together with its endowment of \$100,000 and its property valued at about \$300,000.

WHERE ARE THE ANTIVIVISECTIONISTS?—If, instead of trying to retard the progress of true science, the antivivisection fanatics would take hold of a sensational preacher in Michigan, who kills cats in the pulpit, they might be of some use in the world. According to an account in the *Cleveland Leader*, it was announced that the Rev. W. L. Laufman, of Cadillac, Mich., assisted by Dr. C. E. Miller, would kill two cats in the pulpit of the Methodist church, to illustrate Laufman's sermon on tobacco, on February 7th. On that day the church was packed. Prominent on the pulpit were packages of fine-cut and plug chewing-tobacco. Laufman contended in his sermon that tobacco in any form was bound to fill the user with nicotine and eventually produce death. Spain of to-day, he said, was not the chivalric Spain of Columbus's time, because of the prevalent use of tobacco. He commented also on the decadence of Turkey and France, due, of course, to the use of tobacco; but forgot to mention that Russia was making giant strides sociologically, intellectually and politically, despite the almost universal use of tobacco. Then the cats were brought up by Dr. Miller. An assistant held them while the doctor administered the nicotine. The first one died in a minute and a half, while the attendant held it, after three drops of nicotine had been placed on its

tongue. The next cat, a large one, received only two drops, the purpose being to illustrate the sickness and spasms which the first dose of tobacco creates. A second dose of two drops was given, and in a minute and a quarter the cat was dead. This humble follower of the Lord then announced that next Sunday he would kill some more cats, to show the effects of alcohol, and also have on exhibition the stomach of a drunkard. — *Medical Record*.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, March 3, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 85, scarlet fever 41, measles 194, typhoid fever 6.

THE BOSTON CITY HOSPITAL NURSES' HOME. — The Boston Board of Aldermen have recently appropriated \$100,000, for the purchase of the land at the corner of Massachusetts and Harrison Avenues for a home for nurses, which is to be erected with the generous legacy of Mrs. Ann White Vose, as was recently noted in our columns. The accommodations for nurses in the present home had long been inadequate, and the new building which is now assured, will amply provide, by furnishing quarters for one hundred nurses in addition to those domiciled in the present nurses' home, for the pressing needs of the hospital.

THE INSTRUCTIVE DISTRICT-NURSING ASSOCIATION. — At the annual meeting of the Instructive District-Nursing Association which was held on February 24th, an interesting report was read, showing the large amount of work done by the Association and its nurses during last year. Eleven trained nurses were employed, and they made 46,933 visits among the poor and sick. On 11,751 of these visits the nurses were accompanied by the physicians of the Boston Dispensary, while 35,182 calls were made by the nurses alone, about 4,200 patients being visited. Any practising physician may secure a nurse under the auspices of the Association, by applying at the office at 2 Park Square.

GYMNASIUMS FOR THE INSANE. — Two gymnasiums have recently been completed and equipped for the use of the patients at the McLean Asylum at Waverly. Beside the gymnastic apparatus the gymnasium building for men contains a studio, a reading-room, a large smoking and card-room, two billiard-rooms, a bowling-alley, and two workrooms, where the lighter kinds of manual labor may be carried on. Besides this there is a Turkish bath in the basement under the gymnasium. The women's gymnasium is similar in equipment, except that it has no smoking-room, but instead a parlor with a piano. It will be seen that the gymnasiums are planned to provide amusement as well as opportunities for physical culture for the patients. Regular classes in gymnastics will be organized, and

instruction provided for those interested in acquiring skill in the lighter forms of manual labor. The building ought to provide excellent facilities for the physical culture and mental diversion of the patients, conditions of very great importance for the cure of many forms of mental disease.

NEW YORK.

THE ABUSE OF MEDICAL CHARITY. — The abuse of medical charity in hospitals and dispensaries is receiving unusual attention from the profession at the present time, and a bill having in view the curtailment of this evil has been prepared for presentation to the State Legislature. A meeting was recently held by the East-side physicians for the purpose of discussing the best means of securing the desired end, and a special meeting of the New York County Medical Association for the same purpose was held on February 23d.

A PLAYGROUND ON THE ROOF. — A new public-school building, the first to be provided with a roof-garden for the use of the children as a play-ground, is about to be erected in the crowded tenement district at East Broadway and Henry Street. The entire roof will be surrounded by a parapet wall seven feet in height, and arrangements will be made for the planting of numerous vines and shrubs.

DEATH OF DR. WOOD. — Dr. Willoughby I. Wood, a nephew of the well-known Brooklyn Surgeon, Dr. George B. Fowler, and a young man of great promise, died at Guilford, N. Y., on February 20th. He was born in Brooklyn twenty-eight years ago, and graduated from Bellevue Hospital Medical College, New York, in 1890. At the time of his death he was chief surgeon of the Norwegian Hospital in Brooklyn.

DEATH OF DR. CREAMER. — Dr. Henry A. Creamer, a son of the late Dr. Joseph Creamer, the first police surgeon appointed in Brooklyn, died at his residence in Williamsburg on February 20th, of pneumonia, after a four days' illness. He was twenty-five years of age and a graduate of Bellevue Hospital Medical College.

THE NEW CHAPEL AT BELLEVUE HOSPITAL. — The beautiful Roman Catholic chapel erected on the grounds of Bellevue Hospital by Miss Leary as a memorial of her brother, the late Arthur Leary, was consecrated with imposing ceremonies by Archbishop Corrigan on February 27th. After the religious services Miss Leary entertained the clergy, the Commissioners of Public Charities and a number of other guests at a banquet at the Hotel Waldorf. There has been for some years a handsome Protestant chapel at Bellevue, which was built in memory of the late Mrs. R. H. L. Towusend.

DEATH AT THE AGE OF ONE HUNDRED AND TWO. — Mrs. Mary Newman died on February 20th, at the residence of a daughter, at Locust Valley, N. Y., at the age of one hundred and two. Her extreme age is well authenticated, as the family records show that she

was born in Thenford, Northampton, Eng., on December 23, 1794. She was twice married, and became for the second time a widow in 1873. She leaves 13 children, the oldest of whom is eighty-two years of age, 38 grandchildren, 52 great-grandchildren, and 33 great-great-grandchildren. Up to within a short time of her death she enjoyed excellent health, and even assisted in the work of the house.

A LOW MORTALITY RATE.—Were it not for the fatality of pneumonia, which, as usual at this season, is very prevalent, the death-rate in the city of New York would be exceptionally low. As it is, the mortality has been lower thus far than for some winters past. During the week ending February 27th the deaths from pneumonia amounted to 140, an increase of thirty-nine over the week ending February 6th. In the same weeks the deaths from pulmonary tuberculosis numbered 106 and 109 respectively. While there has been a slight increase in the mortality from scarlet fever and whooping-cough, the number of deaths from diphtheria has decreased from 38 in the week ending February 13th, to 21 in that ending February 27th. During the latter week eight deaths from influenza were reported, the largest mortality from that disease as yet recorded this season. The total number of deaths in the city for the week was 787, against 782 in the week ending February 13th, and 741 in the week ending February 6th.

Miscellany.

OPPORTUNITIES FOR TRAINING IN PHYSIOLOGY.

THE Department of Physiology in the Harvard Medical School offers to four qualified men positions in which training in physiology may be obtained.

It is expected that these men will give the mornings of the collegiate year to research and the afternoons to the direction of under-graduate students in experimental physiology, under the supervision of a professor in the department.

Every effort will be made to instruct the holders of these positions in the ways of framing problems for investigation, in the principles of criticism, in the technical methods of research, and in the manner in which the results of an investigation should be put together for publication. Instruction will be given also in methods of teaching, including the arrangement of lectures, the division of subject matter between the systematic course, covering the entire field and the advanced special lectures, the physiological conference, the Journal Club, the use of the projection lantern in physiological demonstration, and the demonstration of physiological experiments to large and small classes.

The direction of laboratory work will be an important part of the training. The first-year class in the Harvard Medical School is divided into sections of thirty-two. Each section works twenty-four afternoons in experimental physiology, making more than one hundred experiments, such as the influence of temperature on the form of the muscle curve, the phe-

nomena of electrotonus, the compensatory pause of the heart, the use of the artificial eye, the ophthalmoscope, laryngoscope, sphygmograph, etc. The repetition of fundamental experiments in this course, and the great variety afforded by so many experimenters working at the same time, secure to the directors of the work a thoroughness and a breadth of training in elementary physiology scarcely attainable in other ways.

The administration of a large department will be carefully explained. Attention will be given to the cost of apparatus for instruction and research, the problems of construction and maintenance of plant, the care of storage-batteries, the making of lantern-slides, the cataloguing of physiological literature, the importation of apparatus, and many other details essential to the successful operation of a physiological laboratory. Men intending to devote themselves to clinical medicine will, of course, give less time to these things and will concern themselves chiefly with matters bearing directly on their chosen work.

It is evident that these appointments will afford an admirable training to those intending to make physiology or any other of the biological sciences a profession. To the physician they offer a training not less valuable in the opinion of those who believe that research in the fundamental sciences is the best introduction to the higher walks of medicine.

Applicants for these positions should possess an elementary knowledge of physiology and a sufficient training in one or more of the biological sciences to enable them to profit by the instruction offered. Successful applicants are required to take twelve half-days' instruction in the details of the course in experimental physiology, before October 1st of their year of service.

No charge of any kind will be made for the year's training.

The Harvard Medical School will give successful applicants the title of "Assistant in Physiology," and for the direction of the classes in Experimental Physiology will pay each Assistant four hundred dollars.

Applications may be sent to Prof. H. P. Bowditch, Harvard Medical School, Boston, Mass.

Obituary.

EDWARD PAYSON ABBE, M.D.

On Monday, February 25th, Edward Payson Abbe, M.D., of New Bedford, Mass., died, aged sixty-nine.

At a special meeting of the Staff of St. Luke's Hospital, of New Bedford, held Monday, February 25th, the following Resolution was adopted:

The Staff of St. Luke's Hospital desire to place on record their sense of inestimable loss in the death of their colleague and President, Edward Payson Abbe. It is largely due to him that New Bedford has a hospital, and it is largely owing to his zeal and discriminating wisdom that our hospital has reached its present high plane of efficiency. His fidelity to his patients, his loyalty to his *colleagues*, his genial hospitality, and his solicitude for the best interests of the community endeared him to all. We wish to assure his family and the public of our heartfelt sympathy.

For the Staff of St. Luke's Hospital,

GARRY DE N. HOUGH, M.D., *Secretary*.

THE MORTALITY OF INTUSSUSCEPTION.

PHILADELPHIA, February 26, 1897.

MR. EDITOR:—In an effort to determine the true mortality of intussusception in children, and thus eliminate the error incident to a calculation based upon reported (and hence as a rule, successful) cases, I have sent out 500 lists of questions similar to the one enclosed.

INTUSSUSCEPTION IN CHILDREN (UNDER TWELVE YEARS).

Seen by Dr.	In personal practice	In consultation
Age of patients		
Cause of intussusception (polyp?)		
Symptoms.—Tumor	Passage of bloody mucus	
Tenesmus	Vomiting	Intense Pain
Treatment.—Medical	Result	
Mechanical (Injection of air	water	Massage
Result		
Period elapsing from first symptom to mechanical treatment		
Treatment.—Operative (Disinvagination through abdominal	Result	
opening)	Result	
Resection	Result	
Seat of invagination	Amount of bowel resected	
Method of joining intestines	Period elapsing from	
the first symptom to the time of operation		
Results of Autopsies		
Further details not covered by the above headings will be gladly received, such as recovery with passage of slough, etc.		

I have been surprised to find how few men, even those of large experience, have encountered this class of cases. The number thus far reported is scarcely sufficient to serve as a basis for conclusions.

It is in the hope that you may be willing to assist in this work by publishing the enclosed list or one similar to it, and asking your subscribers to forward me their unreported cases, that I write you.

Any help that you may give will be very highly appreciated by,

Faithfully yours,

EDWARD MARTIN, M.D.

A PLAN FOR THE STAMPING OUT OF PULMONARY TUBERCULOSIS FROM THE LAND.

509 FIFTH AV., NEW YORK, February 10, 1897.

MR. EDITOR:—The resolution recently passed by the New York Board of Health, making it mandatory upon physicians residing within the city of New York to report all cases of pulmonary tuberculosis coming under their observation, for the purpose, as President Wilson states, of arriving at statistical results that may be of value in determining the future course of the board, calls up an exceedingly important matter, which it seems to me the various health boards throughout the United States, should take cognizance of, namely, the very large percentage of deaths that result from respiratory diseases. Thirty per cent., I believe, is the estimate given.

That it would be a simple matter to entirely stamp out pulmonary tuberculosis by the removal of all such cases to a dry atmosphere in a high altitude no one who has ever visited Colorado, New Mexico or California can fail to have observed. The wonderful curative influence that high altitude has upon persons suffering from pulmonary tuberculosis is known to every well-read physician throughout the land. I have time and time again conversed with men of wealth, prominent in the affairs of Colorado and New Mexico, who only a few years ago were taken into that country in a condition of extreme emaciation, almost ready to die, suffering from the last stages of pulmonary tuberculosis. To-day these men have not only gained health, but are robust, of large stature, giants in strength and strong in intellect.

What did it? An altitude of from four thousand to six thousand feet and a dry atmosphere. And yet we permit sufferers from pulmonary tuberculosis to walk the streets

of our Eastern cities, tolerating their expectoration *ad libitum*, when it is known that the dry products alone of such expectoration serve as a source of contamination for future cases of pulmonary tuberculosis.

I would suggest that there be established somewhere in the State of New Mexico or Colorado a national home for consumptives. I can picture to myself a beautiful city—something similar to the former "White City" of Chicago—where each State will have its State home. The population of this city, based on the present annual death-rate of persons suffering from pulmonary tuberculosis, would be between 300,000 and 500,000 people.

From conversation with prominent men in Massachusetts, where consumption is rampant, I am led to believe that the State of Massachusetts would infinitely prefer to have a consumptive State home somewhere where there was a possibility that at some time there would be an end to the enormous expense incident to carrying on a consumptive home within its own borders, where they now have such an institution, which is merely the last resting-place of the persons who are received there. People do not go there to be cured; they are supported by the State until such time as death ends their sufferings.

If it can be shown that after a certain period of time the expense of maintaining a State home in a section of country where, and under such conditions, a large percentage of those sent to the home will be cured, would not that be a better plan to adopt than the plan of establishing large hospitals within the limits of the State, which would become, under conditions existing here, the merest makeshift and in no way curative? The Episcopal Home at Denver is a church affair, but fully demonstrates the practicability and desirability of a national home.

I firmly believe that our national representatives would be perfectly willing to take this matter in charge—to allot or assign a certain number of acres of public land immediately adjacent to the foot-hills, say at an elevation of about 4,000 feet, at a point to be selected by a commission to be appointed by Congress. We have plenty of public land available for the purpose not far from the great trunk lines and within sufficient proximity to the foot-hills of the Rocky Mountains to make the matter of irrigation perfectly practicable and with the expenditure of but little money, as convict labor could be employed in bringing the water down from the mountains, which has been done with one of the irrigating systems now being operated in Colorado.

If the full import of this matter were properly placed before our national legislators there can be no question but that a commission would be appointed for the purpose of looking into the question and investigating the proper site for the establishment of such a national home. I believe there will be no difficulty in having this matter taken up and properly carried through, for it must appear perfectly apparent to every right-thinking man that we owe it to ourselves and to our families that we should protect ourselves from the possibility of infection from one of the most fatal of all diseases.

In regard to the maintenance of the several homes and the sanitary and general management of the city, I believe if the government and management of the place were patterned after the general management of the District of Columbia—that is, to be under national control—it would be most expedient and practicable; each State to maintain its respective home and the several State homes to be under the control and management of the United States Government, which will be simply asked to appropriate the land and to furnish the water-supply, the drainage and executive buildings; each State to bear the cost of erecting its own home, plans for the buildings to be submitted to and approved of by the supervising architects.

The medical officers should be appointed to the several State homes after their fitness has been demonstrated for the position by competitive examination by a board selected for that purpose; this measure to be carried out in order to avoid as far as possible all opportunity for medical officers to be sent by the several States in return for political favors. Laws should be passed by the legislatures of

the several States making it mandatory upon every medical man in each State to report each and every case of pulmonary tuberculosis that comes under his supervision, even in its incipient stage, to the health officer of his town or city, failure on his part to report such a case to subject him to a heavy penalty. When such a case is reported that case should be sent at the expense of the State to the State home.

I think sufficient has been said to convey a general idea of the carrying out of this plan, which would not in any way conflict with the establishment in the future of private sanitariums, or interfere with those already established, where it can be shown that the existence of such institutions is not detrimental to the public health. This should be decided by medical officers selected for that purpose.

Our negligence in handling so serious a subject certainly shows a frightful state of ignorance of the condition of affairs, or else an abnormal degree of indifference. It is remarkable what a state of agitation and excitement the public can be thrown into if yellow fever be reported off quarantine, and yet the number of lives lost annually through yellow fever sinks into insignificance as compared with the army of people annually carried off by pulmonary tuberculosis.

If the above plan, or a modification of it, is ever carried out, an object-lesson will be presented in the United States for the whole world to follow. There are many points in Europe available for the carrying out of this plan for the people on the other side of the water.

Very truly yours, ALFRED WALTON.

THE USE OF RINGER'S FLUID.

585 WASHINGTON ST., DORCHESTER, MASS.,
February 25, 1897.

MR. EDITOR:—Mention was made in the JOURNAL of January 21, 1897, page 54, of a modification of Ringer's fluid by Dr. F. S. Locke, the formula being 0.3 gramme CaCl_2 , 0.1 gramme KCl to 1,000 c. c. normal salt solution. This fluid was used by Dr. F. W. Johnson for rectal injection in quantities of about a quart.

A modification of Ringer's fluid has been in constant use in the Massachusetts General Hospital for about two years. The formula is 0.1 gramme CaCl_2 , 0.75 gramme KCl to 1,000 c. c. normal salt solution. This fluid has been used chiefly for intravenous infusion, by means of a canula, in quantities of 500 to 2,000 c. c. Its use in the Massachusetts General Hospital started from a suggestion made to me in 1894 by Dr. Wm. H. Howell, formerly Assistant Professor of Physiology in the Harvard Medical School, who was then repeating some experiments of Sidney Ringer. One set of these experiments showed that calcium salts are essential to the clotting of blood. Another set consisted in passing different fluids through an isolated heart (frog's), and observing the character of the beats and the length of time the beating was sustained by such fluid. Blood serum sustains the beats well and for a long time. A solution of the albumins of the serum without salts does not sustain the beats well, nor does a simple normal salt solution. The addition of a calcium salt alone to the salt solution causes strong beats, which are, however, too prolonged, and therefore inefficient. The addition of a small amount of potassium chloride corrects the character of the beat, and this combination, normal salt solution, plus calcium, plus potassium, will sustain heart beats as well and as long as blood serum.

The idea is very near to supply such a fluid to the circulation in cases of extensive hemorrhage, in place of using simple salt solution, which experimentally, at least, does not sustain the heart so well. Ringer's fluid is 100 c. c. of a .75-per-cent. solution of sodium chloride saturated with calcium phosphate, adding 1 c. c. of a two-per-cent. solution of potassium chloride. This is not convenient, however, for use in surgery, because the boiling necessary for sterilization precipitates a phosphate of calcium. This might

possibly be evaded by sterilizing the ingredients, but it was found in the Massachusetts General Hospital more convenient to use the soluble chloride of calcium. The fluid can be made up in Florence flasks, which can be boiled and the fluid kept sterilized for accident work, and warmed for use by placing in a pail of hot water.

The difficulty of comparing the action of Ringer's fluid with that of salt solution is extreme, as the cases where either is used show such tremendous variations in prognosis independent of any treatment.

It seemed to me when I first used the fluid intravenously in accident cases in the winter of 1894-95, that the effect was more permanent than that of salt solution. Two or three remarkable recoveries from hemorrhage and from shock have occurred with, and possibly because of, its use. It is possible that a modification like that of Dr. Locke containing 0.3 gramme calcium chloride to the litre instead of 0.1 gramme, as used in the Massachusetts General Hospital, is more advantageous; and again, it is possible that one percentage may prove better adapted for intravenous use and another for rectal. It is much to be desired that Ringer's fluid should receive an extensive trial, and, if possible, in such a way that its value compared to that of simple salt solution may be estimated.

Very truly yours,

RICHARD E. EDES, M.D.,
Formerly Surgical Intern, Mass. Gen. Hos.

RECORD OF MORTALITY FOR THE WEEK ENDING SATURDAY, FEBRUARY 20, 1897.

Cities.	Estimated population.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

Deaths reported 2,824: under five years of age 878; principal infectious diseases (small-pox, measles, diphtheria and croup, erysipelas and fevers) 232, acute lung diseases 500, consumption 375, diphtheria and croup 91, typhoid fever 31, measles 20, cerebro-spinal meningitis 17, scarlet fever 12, whooping-cough 11, erysipelas 7.

From measles Chicago 10, New York 8, Pittsburg and Worcester 1 each. From cerebro-spinal meningitis New York 6,

Worcester and Lynn 2 each, Boston, Washington, Cambridge, Somerville, Lawrence, Brockton and Chelsea 1 each. From scarlet fever New York 3, Baltimore 2, Boston 1. From whooping-cough New York 5, Chicago and St. Louis 2 each, Baltimore 1. From erysipelas New York 3, Chicago 2, Boston 1.

In the thirty-three greater towns of England and Wales, with an estimated population of 10,992,524, for the week ending February 6th, the death-rate was 20.8. Deaths reported, 4,375; acute diseases of the respiratory organs (London) 404, whooping-cough 132, diphtheria 69, fever 51, diarrhea 45, measles 34, scarlet fever 30.

The death-rates ranged from 11.3 in Huddersfield to 27.2 in Manchester; Birmingham 20.8, Bradford 19.4, Bristol 23.3, Cardiff 17.8, Derby 19.7, Gateshead 21.2, Leeds 21.5, Leicester 17.4, Liverpool 25.2, London 20.6, Newcastle-on-Tyne 14.6, Nottingham 18.8, Portsmouth 20.3, Sunderland 18.3.

In the thirty-three greater towns of England and Wales with an estimated population of 10,992,524, for the week ending February 13th, the death-rate was 19.6. Deaths reported 4,128; acute diseases of the respiratory organs (London) 373, whooping-cough 108, diphtheria 62, measles 52, diarrhea 49, scarlet fever 35, fever 29, small-pox (London) 2.

The death-rates ranged from 12.5 in Croydon to 26.2 in Plymouth; Birmingham 22.8, Bradford 18.5, Cardiff 12.6, Halifax 14.2, Hull 19.9, Leeds 20.5, Leicester 16.1, Liverpool 25.5, London 18.6, Manchester 23.9, Newcastle-on-Tyne 17.3, Nottingham 21.0, Sheffield 18.8, West Ham 14.5.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 20, 1897, TO FEBRUARY 26, 1897.

Leave of absence for two months, to take effect on or about March 5, 1897, is granted to FIRST-LIEUT. ROBERT S. WOODSON, assistant surgeon, Jackson Barracks, La.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING FEBRUARY 27, 1897.

G. T. SMITH, passed assistant surgeon, detached from the "Adams" on reporting of his relief about March 2d, ordered home and granted two months' leave.

L. H. STONE, passed assistant surgeon (London), detached from the Naval Hospital, New York, March 15th, and ordered to the "Adams."

G. P. BRADLEY, surgeon, detached from the "Indiana," March 3d, ordered home and placed on waiting orders.

N. MCP. FERRELL, surgeon, ordered to the "Indiana," March 3d.

W. F. ARNOLD, passed assistant surgeon, ordered as a member of the medical examining board, League Island Navy Yard.

L. W. ATLEE, passed assistant surgeon, detached as member of the medical examining board, League Island Navy Yard.

SOCIETY NOTICES.

TRI STATE MEDICAL SOCIETY OF IOWA, ILLINOIS AND MISSOURI.—The Society will meet in St. Louis, in the Auditorium of the Holland Building, April 6, 7 and 8, 1897.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, on Monday evening, March 8th, at 8 o'clock.

Dr. Maurice H. Richardson will read a paper entitled: "A Comparison between Hospital and Private Surgery."

Dr. George A. Raymond, by invitation: "Treatment of Congenital Cleft Palate by Mechanism."

JAMES G. MUMFORD, M.D., Secretary, 197 Beacon St.

RECENT DEATH.

JOHN OSBORN DOW, M.D., M.M.S.S., died at Reading, February 22, 1897, aged seventy-four years.

BOOKS AND PAMPHLETS RECEIVED.

Anesthesia of the Trunk in Locomotor Ataxia. By Hugh T. Patrick, M.D. Reprint. 1897.

Cyclone Neuroses. Imperative Conceptions. By C. H. Hughes, M.D., St. Louis. Reprints. 1897.

The Annual Statistics of Manufacturers, 1895. Tenth Report. Boston: Printed by the State. 1896.

The Appendicitis Craze and the Grape Cure. By Irving C. Rosse, M.D., Washington, D. C. Reprint. 1896.

Twenty-sixth Report of the Board of Trustees of the Connecticut Hospital for the Insane. State of Connecticut, 1896.

Disinfection of Rooms after Contagious Diseases. By U. O. B. Wingate, M.D., of Milwaukee, Wis. Reprint. 1896.

Twenty-sixth Annual Report of the Bureau of Statistics of Labor, March, 1896. Boston: Printed by the State. 1896.

Binasal Hemianopsia, with the Report of an Additional Case. By Clarence A. Veasey, A.M., M.D., Philadelphia, Pa. Reprint. 1897.

Diseases of the Rectum as a Cause of Auto-Infection, with Report of Cases. By J. R. Pennington, M.D., Chicago. Reprint. 1897.

Constitution, By-Laws, Standing Rules, Yearly Organization, Necrology and List of Members of the Maine Medical Association. 1896.

Notes on Some of the New Remedies Used in Diseases of the Skin. By L. Duncanson Bulkley, A.M., M.D., New York. Reprint. 1896.

A Review of Some Interesting Points in Surgery Observed during the Six Months ended June 1, 1895. Reviews of Some Points of Surgical Interest in Abdominal Cases. By Edmund J. A. Rogers, M.D. Reprints. 1895-96.

Forty-first Annual Report of the Executive Committee of the Hartford Hospital, including the Twelfth Annual Report of Old People's Home and the Nineteenth Annual Report of the Hartford Hospital Training-School for Nurses. Hartford, Conn. 1896.

A First Series of Fifty-four Consecutive Ovariectomies with Fifty-three Recoveries. By A. C. Butler-Smythe, F.R.C.S. Ed., F.R.C.P. Ed., Senior Surgeon to the Grosvenor Hospital for Women and Children; Senior Surgeon to Out-Patients, Samaritan Free Hospital for Women and Children. London: J. & A. Churchill. 1897.

Hand Atlas der Anatomie des Menschen. In 750 Theils Farbigen Abbildungen, mit Text mit Unterstützung von Wilhelm His, Professor der Anatomie an der Universität Leipzig, bearbeitet von Werner Spaltholz, a. o. Professor an der Universität Leipzig, und Custos der Anatomischen Sammlungen. Zweiter Band, erste Abtheilung. Leipzig: Verlag von S. Hirzel. 1896.

Post-Mortem Examinations in Medico-Legal and Ordinary Cases, with Special Chapters on the Legal Aspects of Post-Mortems, and on Certificates of Death. By J. Jackson Clarke, M.B. (Lond.), F.R.C.S., Assistant Surgeon to the Northwest London Hospital, Pathologist and Curator of the Museum at St. Mary's Hospital. London, New York and Bombay: Longmans, Green & Co. 1896.

Traité de Therapeutique et de Matière Médicale, contenant les Principes de la Nosologie Naturelle, de la Prophylaxie et de la Pharmacologie, d'après les Leçons Proférées à l'Hôtel-Dieu de Paris. Par Victor And-Honi, Directeur de la Bibliothèque Aldine, Médecin de l'Hôtel-Dieu, Professeur Particulier de Therapeutique et d'Hydrologie Médicale, Médecin des Eaux de Vichy. Paris: G. Steinhell, Editeur. 1897.

Autoscopy of the Larynx and the Trachea. Direct Examination without Mirror. By Alfred Kierstein, M.D., Berlin. Authorized translation (altered, enlarged and revised by the author) by Max Thorner, A.M., M.D., Cincinnati, O., Professor of Clinical Laryngology and Otology, Cincinnati College of Medicine and Surgery; Laryngologist and Aurist, Cincinnati Hospital, etc. With 12 illustrations. Philadelphia: The F. A. Davis Co. 1897.

Anomalies and Curiosities of Medicine, Being an Encyclopedic Collection of Rare and Extraordinary Cases and of the most striking instances of Abnormality in all Branches of Medicine and Surgery, derived from an Exhaustive Research of Medical Literature from its Origin to the Present Day. Abstracted, classified, annotated and indexed by George M. Gould, A.M., M.D., and Walter L. Pye, A.M., M.D. With 295 illustrations in the text and 12 half-tone and colored plates. Philadelphia: W. B. Saunders. 1897.

Principles or Guides for a Better Selection or Classification of Consumptives Amenable to High Altitude Treatment and to the Selection of Patients who may be more Successfully Treated in the Environment to which they were Accustomed Previous to their Illness. By A. Edgar Tassey, M.D., Adjunct Professor of Diseases of the Chest in the Philadelphia Polyclinic and School for Graduates in Medicine, and Consulting Physician to the Central Branch of the Y. M. C. A. Gymnasium. Philadelphia: P. Blakiston, Son & Co. 1896.

A Pictorial Atlas of Skin Diseases and Syphilitic Affections in Photolithochromes from Models in the Museum of the Saint Louis Hospital, Paris. With explanatory wood-cuts and text by Ernest Besnier, A. Fournier, Tenneson, Hallopeau, Du Castel, Physicians to the Saint Louis Hospital, with the co-operation of Henri Foulard, Curator of the Museum; Secretary L. Jacquet. Edited and annotated by J. Pringle, M.B., F.R.C.P., Physician to the Department for Diseases of the Skin at the Middlesex Hospital, London. Part VII. London: The Rebman Publishing Co. Philadelphia: W. B. Saunders. 1897.

GENERAL PARESIS.¹

BY GEORGE F. KEENE, M.D., HOWARD, R. I.,
Physician to the Rhode Island State Insane Asylum.

EVERY disease has its identity. It matters not whether it be one of those terrible scourges that have decimated the human race, or the simpler exanthems of childhood; each is known and recognized by peculiar manifestations. It needs not in many cases the experienced eye nor the acute perception of one skilled in medicine for a correct diagnosis. It is the domain of the expert to detect what the common mind cannot or does not perceive. In this he is aided not only by special training, but by those instruments of precision which will enable him to see what to others is invisible, to hear what to others is inaudible, and to feel what others cannot touch. He summons to his aid not only every sense perception, discarding not even that of smell, but he has learned to marshal them in such order that the judgment seldom fails to determine or classify the problem presented at the bar of consciousness. There are three factors which must enter into the diagnosis of every malady, namely, the disease, the patient and the doctor. Important as is the disease *per se*, its phenomena will be striking, commonplace or obscure to a large degree, according to the kind of man exhibiting them; so also will the diagnosis of perplexing pathological conditions depend much upon the acumen, as well as the experience of the investigator. There are certain diseases whose diagnosis depends on the manifestation of a single symptom, or perhaps it would be better stated to say that the presence of certain single symptoms predicates certain pathological processes; for example, the crepitant râle and the rusty spit are classical and pathognomonic.

Diseases of the body, however, have no comparison with the diseases of the mind, either in their ease of classification or definiteness of causation. Their pathology is as yet largely relegated to the realm of speculation, their symptomatology is much more decidedly influenced by the temperament of the individual attacked. Symptoms are many times obscured and often concealed that might suggest the true nature of mental disease. The consciousness that a court or some legal process must be appealed to soon after the physician is called, does not tend to simplify the matter of diagnosis or re-enforce the method of treatment. It is in the domain of mental medicine, then, that the ordinary physician is most sorely tried, both as to diagnosis and treatment. Here he realizes, if never before, the limitations of medicine as a science. He looks for some signal symptom, some pathognomonic sign; the symptoms of mania, melancholia and dementia he has learned to differentiate, but he finds them all in his first case, or he finds them not all, and yet feels certain that he is dealing with a case of mental alienation. Perhaps he is tempted to hold for advisement his decision, meanwhile invoking the protection of that euphemistic phrase "nervous prostration," to characterize the condition of his patient.

There is no disease probably more protean in its type—more easy at times, or more difficult at others, of diagnosis than that disease of the mind known as general paralysis, general paresis and parietic dementia;

and it may simulate almost any or all forms of mental disease in the same subject. It is popularly known under the head of "softening of the brain," furnishes a goodly percentage of all cases of insanity, and is pre-eminently a disease of civilization and of the white race. Less than a century ago, before medicine had become completely emancipated from the thrall of superstition and ignorance, this disease was unknown and unrecognized, in spite of the claims that the English alienists, Perfect and Haslam, had drawn attention to its characteristic symptoms among the insane at the close of the seventeenth century. It was to the great Frenchman, Esquirol, an illustrious predecessor of Charcot at the Salpêtrière, and to the pupils of Esquirol to whom is due the honor of first recognizing under the designation of "incomplete general paralysis," a disease, which, according to Hammond, is the most common, perhaps, of all mental affections, and whose discovery was believed to be "the greatest step in advance that is recorded in the history of mental disease." The new disease was extensively investigated by many observers, inaugural theses were founded upon it, and the whole world of medical science as much stimulated as it is at the present day by the revelations and adaptations of the x-ray. Although Bayle had accurately described this disease in 1822, defined its symptoms and classified them into three groups, for example, one of monomania, another of mania and a third of dementia, it was not until thirty-six years after that the French Medico-Psychological Society endorsed his views after a long and stormy discussion, asserting their recognition of "the principle of the essentiality of general paralysis." The chief opposition came from those who saw in this disease two distinct entities, a paralytic dementia, the chief factor, and one of the stronger, more active forms of insanity, such as mania or melancholia, as an accessory factor; and thus is added a paralytic insanity to a paralytic dementia. These dualists are by no means extinct; commencing with Requin and Baillarger in 1846, they have an illustrious supporter to-day in Dr. Regis, whose "Manual of Mental Medicine" was crowned by the Faculty of Medicine of Paris, and received the Chateaufort Prize in 1886.

The early pathology of this disease was believed to be a chronic meningitis; but with the researches of the microscope the minuter changes in the tissue elements of the brain were recognized and recorded. When Ferrier and others, by patient and painstaking research and experiment, had demonstrated the now well-established theory of cerebral localization, this, too, was summoned to the aid of the alienist to assist him in explaining the different and diverse symptoms of this protean disease. There is no doubt but what the near future will see either the history of this disease rewritten, or the dualist theory gaining fresh adherents to its certainly more logical doctrine.

He who has watched the development, duration and termination of this disease in many individuals cannot but be impressed with the fact that these cases travel along two distinct progressive paths, each terminating in the same way—some rapidly; some slowly; some with the attendant fire of mania exhausting the vital units faster by the violence of the mental and physical strain; some, and they are by no means few, subsiding into mental oblivion with scarcely a protest from the deteriorating mind, and the ruin which is wrought is

¹ Read before the Providence Clinical Club, November 25, 1896.

only registered quiescently in progressive loss of function of muscles, nerve and brain. Every nerve tissue, from the cerebral cortex to the nerve terminals of the periphery, and even the ganglia of the sympathetic, may be invaded by the degeneration which attends this disease. The vestiges of its destructive advance are found ascending and descending the spinal cord, permeating the surface convolutions and penetrating the basal ganglia of the brain. Each area invaded responds to and discloses in its own peculiar way its ruined integrity.

The etiology of this disease, which might be called pre-eminently a disease of our age, has been the subject of discussion and difference among alienists of the present day. With regard to the more contributory factors, such as heredity, sex, age and occupation, all are agreed, but with regard to the main or exciting cause there is still much dispute. The contention comes upon the real causative relation of syphilis.

Statistics have been resorted to by more than seventy writers on this subject, and have been used both on the affirmative and negative side of the question at issue, with the classical success of being able to prove everything or nothing, with a well-handled and properly constructed statistical argument. These writers have shown syphilitic history to obtain in every proportion in parietic dementia from the 13 per cent. of Nicoulaï to the 100 per cent. of Kjellberg. Asylum records have been appealed to, both public and private; and one writer, not satisfied with the 19 per cent. of actual syphilitic histories recorded at one asylum, assumes 41 per cent. more to average up to his own belief of 60 per cent. that should exist. Where there is so much difference of opinion it is certainly hard to determine the exact relationship of these two diseases; and whether syphilis is a predisposing or a precursory cause, is a question to which all sorts of logic has been applied. One author states that out of 20,000 cases of syphilis only one per cent. became insane, and not one a parietic. Again, says another, among the native Egyptians where syphilis is exceedingly prevalent, not a case of general paralysis has been reported. (It might be stated parenthetically, after such an assertion, that native Egyptians are a colored race, and this race is peculiarly exempt from this form of mental disease.) Another writer reports nine cases of paresis in which syphilis developed after the manifestation of the mental affection.

But the crowning and, seemingly, convincing argument of the objectors to the syphilitic etiology is the fact of the utter futility of mercurial or anti-syphilitic treatment in this disease. The same argument, however, could be used with considerable force against the syphilitic origin of locomotor ataxia, which origin is most universally admitted at the present time. Sachs is responsible for the statement that "The very frequent development of tabes after dementia paralytica and of dementia paralytica after tabes, proves the close relationship between these two diseases; and since tabes is beyond a doubt a form of syphilitic disease, there is sufficient ground for thinking that dementia paralytica bears the same etiological imprint." Obersteiner, of Vienna, has recently affirmed that syphilis is a direct factor in the development of general paresis and regards this affection of the mind as one of the later exhibitions of syphilis. Regis has collected 14 cases of this disease occurring in individuals under twenty years of age; in six of these syphilis was hereditary, in one

it had been acquired, and in two cases there were good reasons to suspect there had been an initial lesion.

The tendency of discussions among medical men for the past five years has been rather to affirm the syphilitic origin of this disease, while alcohol and other toxic agents have been relegated to a subordinate place as contributory rather than exciting causes. One has poetically put the three causes of general paralysis as "wine, women and worry." The arguments of those who would have us believe that alcohol is a prominent causative agent, in this as well as many other diseases, is drawn from purely theoretical dogmas and the production, as they would have us believe, of general paresis in dogs by daily dosing with alcohol. The trend of medical opinion to-day is not only toward the syphilitic origin of this disease in the majority of cases, but also to the doctrine that nearly every case of paresis would present an antecedent history of syphilis, if the investigation could only be carried far enough. The fact that even recent syphilis is the frequent cause of a pathological condition closely resembling general paresis in all respects, has forced those who are loath to admit the causative relation of luetic disease to adopt "pseudo general paresis" as a designation for this class of cases.

The main reasons for regarding syphilis as the exciting cause of general paralysis of the insane may be stated categorically in the following propositions, namely, a large number of syphilitics develop general paresis; this form of mental disease is rare among women; it is rare in rural districts and among religious orders; a syphilitic history can be elicited from the majority of parietics; locomotor ataxia of well-established luetic origin is at times associated with this disease; syphilitic antecedents are usually found in those young persons who are occasionally attacked with parietic dementia.

But without pursuing further the interminable, not to say profitless, discussion concerning its etiology, let us examine it as it is—study as it presents itself the picture of the disease with all its lights and shadows.

The picture at first presented is indistinct, poorly focused as it were. The patient does not appear to the casual observer different from what he should be or from other men; but to his family, to his employers, to his intimates, he is not the man he was. There is a something which cannot be explained, a vague metamorphosis. He lacks courtesy and consideration for those who have been dear to him. He becomes thoughtless, irritable, absent-minded and has little moral lapses where previously he was most correct. If a skilled artisan, his hand begins to lose its cunning, and he turns out imperfect work without recognizing it as such. Is he a musician, his execution lacks the customary expression, the vivacity is gone, and with it that finer touch which might once have savored of genius. The acute business man begins for the first time in his life to squander. The model and virtuous husband and father begins to frequent brothels. The punctilious gentleman forgets his appointments and becomes rude in his social relations; or without motive and without cunning, but possibly with some display, appropriates things not his own and not needed. In other words, the picture presented to us by the patient is one of faulty fine adjustment to environment. Possibly he only complains of headache, dizziness, perhaps fainting-spells, or more rarely, true *petit mal*. He may have violent, uncontrolled outbursts of anger,

alternating with obtrusive, silly egotism, leading to all sorts of improprieties or even immoralities. He loses flesh and strength, it may be. He is troubled with sleeplessness, yet no one for a moment thinks him insane. His friends call a physician, and he is believed to be suffering from overwork, nervous prostration or cerebral hyperemia, and is perhaps advised to take a change of air and scene.

These are the symptoms of the early, the first or prodromal stage of general paresis. There are no striking, no pathognomonic, no signal symptoms. We are simply confronted with a changed condition. The man, not as compared with others, but as compared with himself, has deteriorated; the deterioration may possibly be undetected, even by an expert, from personal examination; but trustworthy information of what he has been, compared with what he is, will often be the sole means of diagnosis, should we recognize from this a diseased individuality. In this early stage, however, if there are any symptoms which are in any sense diagnostic, they are, impaired attention and transitory loss of memory,—the exaggeration of the "I know but can't think" condition. In fact, the same mental symptoms that characterize age and decrepitude are here noticed. The same stories are told over and over again to the same person. Perhaps the patient is trusted with some trivial commission, a bundle, it may be, to leave somewhere, and he carries it back home with him, forgetting where he got it or what was the errand. Any new business or new details of old business are not entered upon with interest, but are apt to be left unfinished. There are, as one has aptly put it, "lacunæ in the conceptions," and directions have to be repeated again and again before the attention is sufficiently aroused to take them in. In a word, thought is sluggish, perception dulled and memory halting. Not all cases pass through this introductory or prodromal stage, but typical cases do.

The length of the first stage has been variously given us from several months, the usual duration, to several years, an exceptional duration. This stage is often passed unnoticed; and seldom are physicians called in thus early unless, as a result of the patient's deeds, some action at law, either civil or criminal, arises, which renders medical examination of the patient's mental condition necessary.

Often has the general parietic been sent to prison as a punishment for crimes which are only the moral lapses of the prodromal stage of this disease. To recapitulate, the symptoms of the first stage are those of an exhausted and over-irritated brain, giving threefold manifestations, namely: intellectual, as recorded in lapses of memory and loss of attention; moral, as exhibited in forgetfulness of social relations, negligence of dress, debauchery, grossness, peccadilloes and criminal acts; physical awkwardness, unskilful work, with possible vertigo and fainting-spells. Thus, we see, even at its inception, there is a vague impression given of the points of attack, and the course ultimately to be pursued by this disease.

The second is the active or stage of recognition. The symptoms up to this time may have been insignificant and unnoticed, but now there commences a new phase, where the physical deteriorations of the preceding stage are more strikingly manifest, and for the first time the muscles of articulation begin to lose little by little their power of coördination. The speech is blurred or slow and hesitating, the lips

twitch, the tongue trembles; there is a fine tremor in the hands and fingers; the handwriting is changed, the finer lines are wavy and broken. The speech lesion is the most common and diagnostic symptom in this disease, and the defects are of two totally different kinds. The one most frequently observed and called paralytic, is a slow, hesitating, stammering, staccato-like speech or mouthing of words. The other, called ataxic, is a species of incoördination, or a confused, incorrect speech, the labials and linguals being only imperfectly pronounced or not pronounced at all. It is the thick speech of the drunken man; and in fact, this stage of the disease is so similar to the manifestations of intoxication that occasionally a parietic has been taken to a police station for drunkenness, when it was but symptoms of his mental malady. There is the same incoördination of muscular action exhibited in the gait that is found in other muscular action, and the patient is unsteady on his feet, rather shambling in his gait. There is usually a marked intention tremor exhibited, best perhaps in the muscles of the face when an attempt is made to pronounce a difficult word, especially if the patient gets earnest or a little excited. There is in talking sometimes so much marked muscular ado, twitchings and tremblings of the upper lips and muscles of the face, that it is a veritable *montes parturiunt* for the birth of a word. The eyes, also, in many cases are affected with the same parietic taint; and the pupillary phenomena are quite characteristic, having received so much attention that each condition has been accurately described and has received a special designation. Perhaps one of the most important pupillary manifestations is the Argyll-Robertson symptom or "reflex irido-plegia." If the patient's pupils, when tested with light, show no change and yet contract and dilate on accommodation to near and distant objects, we have the form of pupil just mentioned, which is a symptom of great significance in the diagnosis of this form of mental disease. Again, both pupils may be exceedingly small, uninfluenced by changes in light, like the opium pupil, technically known as a condition of "spastic myosis." This condition is more frequently found where locomotor ataxia is associated with the parietic condition. Occasionally the pupils may be widely dilated, acting very slowly or not at all to light; this condition is known as "paralytic mydriasis," and is usually associated with more or less retinal disease and blindness. Again, the pupils may be found to have a loss of the normal consensual movements: for example, in healthy eyes, if one is covered and the pupil of the uncovered observed, it will be found to slightly dilate, and on uncovering, this opposite pupil will slightly contract synchronous with its fellow. This phenomenon is undoubtedly from sympathetic action of the two pupils, and is called the "consensual reflex," which is lost sometimes early in parietic states. There is another pupillary reflex excited normally by pinching the skin contiguous to one of the eyes, or stimulating it with an electric brush. In health such stimulus is followed by a slight dilation of the nearest pupil, or sometimes both pupils. This is known as the "sympathetic reflex," and in paralytic dementia is early found wanting.

The face, then, must be closely examined to find the indices of parietic advance. The lips, the tongue, the eyes, not only separately indicate the advance of deterioration, but the expression becomes changed, dead,

petrified, as it were. There is more or less ocular divergence, the two halves of the face become dissimilar in expression; the naso-labial fold is seldom as well marked on both sides; in fact, it is often obliterated on one side. From a state of repose, the forehead wrinkles irregularly, the eyebrows lift unequally, the cheeks rise tremulously. The occipito-frontalis, corrugators of the eyebrows, elevators of the upper lip, constrictors of the mouth and eyes, and elevators of the chin (or Darwin's grief muscles, as they are sometimes called), seem to start off of themselves and without order when articulation is attempted, the general expression being one of pain.

While progressive paresis, with dementia, is the soul of this disease and in a large number of cases the only phenomena, still there is associated with it in over half the cases, some form of insanity, or some active insane manifestation. So certain is the one, however, and so uncertain the other, that the paralytic dementia has been separated out by many able alienists (as was before stated), and the disease believed to be a dual entity. So Regis of the present day is the able exponent of this theory of some of the early French alienists, but more recently of Baillarger, and states in his excellent work on insanity: "As a partisan with M. Baillarger, of the dualist theory of general paralysis, which seems to me to best correspond with facts, I believe that the disease in its most perfect, uncomplicated and essential type is represented clinically, not by this or that delusional form, but, on the contrary, by general paralysis without delusions, by a paralytic dementia essentially made up of a dementia and a progressive paralysis."

The most marked and usual form of insanity accompanying the second stage of general paresis is characterized by mental exaltation. To the feeling of exhilaration — of *bien être* — of the prodromal stage is added, perhaps, maniacal excitation, with ambitious delusions, motor activity and tendency to all kinds of excess; ideas of grandeur, delusions of power; illogical and absurd ideas of wealth and greatness, which at once stamp them as the vaporings and vagaries of the paretic. Nothing in his consciousness militates against his position of absurd aggrandizement. His delusions readily change from one form of grandeur to another, without the slightest regard for their inconsistency. His environment is nothing; he adapts it to his condition; his fancy moves the walls of his room out, transforms his domicile into a palace, peoples the hall with his vassals, transmutes the baser metals into gold, with which he decorates himself, and imagination runs riot with his inflamed mind.

This is mania, it is not necessary to the disease, but sometimes completely masks the degenerative phenomena and cuts off the patient by its violence, when the diagnosis of paresis has scarcely been made. Often this is the very initiatory manifestation; and it is no uncommon thing for the experienced asylum physician to occasionally transfer his diagnosis from acute mania to the episodic mania, associated with paresis, when the subsiding wave of violence reveals something more than its own devastations. Melancholia may, also, either in the hypochondriacal or simpler forms, be associated with a well developed paresis, or may, like mania, be the introductory episode.

There are certain convulsive seizures that sooner or later obtain; and their advent, in a majority of cases, marks the opening of the closing scene, which has

been categorically termed the third or terminal stage of the disease. Not but that the paretic may have had seizures or "fits," as his friends tell you, before, or the first symptom noticed may have been an epileptic fit or an apoplectic seizure; but in the regular order of the disease the place for the gravest symptoms is near the close; and these fits are no insignificant symptoms when repeated at near intervals. The terminal stage, ushered in by convulsions, cerebral congestions or by gradual, almost imperceptible change, is the stage of hebetude, of gross dementia, when the patient walks with difficulty, becomes self-absorbed, because all the sense avenues between the ego and the outside world are becoming blocked and the central station is becoming disorganized. The reflexes are now sluggish; the animal functions embarrassed. The patient becomes untidy; has a tendency to sleep; eats inordinately, perhaps, and with animal grossness, hardly stopping to masticate the food; becomes almost comatose at times, perhaps suddenly hemiplegic or monoplegic, which, however, soon disappears or becomes greatly diminished. He may have a severe attack of apoplexy, with its sudden onset, stertorous breathing and muscular relaxation or paralysis. This attack does not immediately cause death, but frequently is recovered from and sometimes is repeated as many as a dozen times before death supervenes. The true epileptic convulsion is more frequent, however, going through all the classical stages from the cry to the tonic and clonic convulsions and bloody frothing at the mouth. The convulsions, however, are often limited to one side or one limb, and may be in rapid series or a continuous status, exhausting completely the vital force.

The duration of this disease is usually from three to five years; those exceptional cases which cover many years may start with an ascending sclerosis like locomotor ataxia, or may have been preceded with some other form of insanity to which paresis is the finale. Again, it may itself be of the circular or alternating type, with long remissions.

The pathology of this disease has been variously described from a meningo-encephalitis to an endarteritis. The more recent authors, and chief among them Bevan Lewis, have demonstrated that the initial change in this disease is in the vascular tissues, pre-eminently those of the pia mater and the perivascular lymph spaces of the cortex. The change consists in cell proliferation in the lymph sheath, embracing the smallest blood-vessels, and is a true inflammatory change, followed as elsewhere by free exudation into the meshes of the pia. When atrophic changes occur in the cortex, this effusion becomes increased and perhaps compensatory. A further stage in the pathological change is extraordinary development of connective tissue pressing upon the nerve elements, causing their degeneration and disappearance; while the last change of all is a general shrinking of the cortex. The essential points established by pathological investigations, and which may ultimately be of some aid in suggesting a line of treatment, are, first, extra vascular inflammation; second, pressure upon the minute arterioles by the inflammatory products; lastly, exudation, degeneration and atrophy.

It would hardly seem possible that bacteriology had much to do with this disease; yet in the last number of the *American Journal of Insanity* is an account of Dr. Piccinino's investigations, with sections of the

cerebral cortex, from five undoubted paretics. He made very thin sections and then subjected them to a modification of Lustgarten's stain, and, "When by this method the decolorization could be arrested at the point of leaving a slightly violaceous tint, Piccinino was able to see clearly and in large numbers a rather large bacillus, twice as long as broad, sometimes isolated, sometimes in twos or threes, often slightly or strongly curved." The *Journal* says: "These results, if confirmed by other observers, have an important bearing on the syphilitic theory of paresis, and also are suggestive as to the significance of Lustgarten's bacillus, the connection of which with specific disease has not heretofore been considered fully proven."

The diagnosis of this disease is not difficult if it has become well established upon a typical course. The disease may be, however, and often has been, confounded with many others, for example, other dementias, such as post-paralytic dementia, organic dementia from gross brain disease (such as tumors and the like); other paretic conditions, such as cerebrospinal multiple sclerosis and pseudo-general paralysis; other insanities, such as acute mania, some forms of alternating insanity or melancholia of hypochondriacal character. With regard to the dementias, post-paralytic dementia usually occurs in patients beyond the age of fifty, while paretic dementia is pre-eminently a disease of middle life; nor is hemiplegia usually lasting in paresis. Organic dementia, from tremors and the like, does not give the diffused symptoms of paretic dementia; and there are, beside, retinal changes, persistent headache and vomiting, to characterize cerebral tumor. With regard to other paretic conditions, multiple sclerosis has an intention tremor peculiarly its own, and rarely ever is it associated with dementia. Pseudo-general paralysis is not so easy to differentiate. This name was adopted to mark those cases which are similar to general paresis, except that they yield quite readily to treatment and are the result usually of recent syphilis or alcoholism. In these cases the history is a great help; and while it may be impracticable or impossible to differentiate this from true paretic dementia, the issue will very soon determine the diagnosis under appropriate treatment.

Other insanities may be confounded with the insanity often associated with paretic dementia, for example, the maniacal episodes may be mistaken for true acute mania; yet when there is a good antecedent history, and where there is no mental weakening, or where there is a general air of *bonhomie*, the distinction might possibly be made. With regard to differentiation from alternating insanity, the history of previous attacks, or at least of the cycle, will render the diagnosis easier. Melancholia may be sometimes confounded with the melancholia that is occasionally associated with or manifested in general paralysis. The absurdity of the hypochondriacal delusions will usually suffice to set aside the simpler insanity.

In the examination of a patient it is important to get a history as accurate as possible, in order to establish or eliminate all syphilitic taint. Determine the power of attention by asking the patient to repeat the alphabet. If he is a paretic he is likely to make a skip. Ask him to write his name, a verse from some familiar song or a few sentences of the Lord's Prayer. If he has become paretic at all, these tests will usually detect it. Ask him to pronounce such words as "probability," "artillery," "differentiation," "national in-

telligencer." Ask him to whistle. If the tongue or lips are paretic these tests will detect it. Test the pupils for light and accommodation. Test the reflexes: one of the first to be lost is the cremasteric. Stroke the skin on the inside of the thighs quickly, and if the cremaster does not respond it is suspicious, as in 94 per cent. of paretic cases it is very early abolished. Press the ulnar nerve at the elbow: in a large number of cases it is but little sensitive. Watch for intention tremor; make the patient close his eyes and touch the end of his nose with his finger. Look for the Romberg symptom; make the patient stand with eyes shut and heels together and watch closely for swaying. Omit no little detail that will give you an inkling of a paretic condition anywhere in the body. The dementia will make itself apparent by engaging your patient in conversation.

With regard to treatment, anti-syphilitics should be tried, and especially the iodides, sometimes digitalis, ergot and strychnia. Sequestration is imperative, as there is no form of insanity which has greater possibilities at times for harm to the individual or the community than this.

The surgeon, who in the past decade has been doing many wonderful and almost impossible things, has not hesitated to invade the domain of mental disease; emboldened by the seeming promise attending the excision of the micro-cephalic skull of idiocy, he has at last turned his attention to the problem of operative relief for general paresis, if not of cure. The operation was first suggested by Dr. Shaw, of London, in 1889; and the same year Dr. Cripps trephined one of Dr. Shaw's patients, who reported the case some months after as cured. The patient was in the second stage of the disease, and was trephined over the fissure of Rolando about two inches external to the longitudinal sinus. Dr. Batty Tuke was the next to operate; but the case, a very unpromising one, in the third stage, was only temporarily relieved. Dr. Tuke, however, has great confidence in the working theory of the operation, namely, the relief of pressure, and he later suggested laminectomy with permanent drainage. This operation has not been attended with any very brilliant results, because permanent drainage is difficult and sepsis almost unavoidable in these cases.

Dr. Warren L. Babcock, however, in the July number of the *New York State Hospitals Bulletin*, describes a new operation which is called "The Babcock Operation for the Relief of Intra-cranial Pressure." He also reports some cases where the operation has been attended with sufficient success to warrant its further trial. His description of the operation is as follows: "Table is first prepared by placing upon it a firm hair mattress, covered with a rubber sheet which has been washed in a solution bichloride mercury 1-1000. Upon this the patient is placed, in nightgown, on right side with knees flexed on abdomen, so as to separate lumbar vertebrae posteriorly. Lumbar region is cleansed with suds and water and disinfected with creolin or solution of chlorinated soda. A small sized aspirating needle, four inches in length, is disinfected in solution acid carbolie, 1-20. Two or three drops of a one-per-cent. solution of cocaine are injected one half-inch to the right of the spinous process of first or second lumbar vertebra. Needle is inserted to the right of median line, between first and second or second and third lumbar spines and directed upward and inward, until it enters interval between lamina

and then pushed forward into subdural space. As soon as this is entered the fluid oozes forth from the needle in drops at a rate depending on degrees of intracranial pressure. Head of needle is connected with sterilized glass tube and fluid conducted to a clean metric graduate. The operation lasts from fifteen minutes to two hours, depending on rate of flow, and the patient suffers little discomfort." He reports 14 punctures in 12 cases, with varying results, over 50 per cent. of the cases being temporarily improved. It is certainly an operation worth a trial in this hopeless disease.

Let us hope that the future, with its possibilities, may have something yet in store for a better understanding of this mental malady; that the means may yet be put in our hands to more successfully cope with this most distressing and most forlorn manifestation of a mind diseased.

DISCUSSION.

In the discussion which followed the reading of Dr. Keene's paper, DR. WILLIAM A. GORTON, of the Butler Hospital, said:

MR. PRESIDENT AND GENTLEMEN:—The very complete paper of Dr. Keene leaves so little to be said that one feels it presumptuous to attempt a discussion of it. I am pleased to see that the general practitioners of Providence are showing so much interest in mental disease, and especially pleased that Dr. Keene has found the time to so concisely, clearly and exhaustively set before them the subject of paresis as he has this evening done. I feel that I may perhaps be permitted to speak briefly of paresis and syphilis, as the intimate relations between the two diseases do not, it seems to me, always receive from even specialists the consideration which their importance demands.

I well remember, that in 1878, when I first began the serious study of insanity, I learned that paresis was a disease almost always due to sexual excesses, but almost never to syphilis; that, indeed, when to sexual excesses syphilis was added, as syphilitic brain disease simulating paresis often developed, but this was called the pseudo-paresis of syphilitic origin. To-day, most observers are agreed that paresis is, in the vast majority of instances, a disease of distinctly syphilitic origin. The recent exhaustive study of the disease made by Hirschl in Krafft-Ebing's psychiatric clinic in Vienna, goes very far toward proving that paresis is in more than eighty per cent. of the cases due to syphilis and possibly in an even larger per cent. is the result of that disease. He further discusses other supposed causes, such as traumatism, overwork, alcohol, simple venereal sears, etc., and concludes that they are but rarely the real source of true general paralysis. As Dr. Keene has told you, the French School still holds to the dualistic theory, which is somewhat opposed to the results of the studies of Hirschl, and of many others both here and abroad. It is but fair to say that Peterson and Syms, of New York, concluded from a study of a comparatively large number of cases that syphilis was the cause in less than fifty per cent. of them. So far as my own observations go, I am obliged to say that they completely sustain the statistics of Hirschl. Formerly I had different views, but I must frankly confess that they were founded upon the results of imperfectly ascertained histories.

Much has been written on the subject of paresis during the past ten years, and the fact that the syphilitic origin of it grows more and more to be advanced as cases have been more carefully investigated shows to my mind at least, that we must admit pretty much the same connection of syphilis with general paralysis that Erb has established between it and *tabes dorsalis*. Several rather interesting cases of paresis occurring in syphilitic subjects have been reported, going to prove that in a certain percentage of cases showing but slight secondary symptoms, the tertiary period has consisted wholly in the development of general paralysis, and

the inference has been drawn from them that the latter disease might have been averted by more vigorous treatment of the original affection. The number of cases thus far collected as bearing upon this point is too small to warrant any very definite conclusions.

That general paralysis has not been cured by anti-syphilitic treatment has been sometimes urged against its syphilitic origin, but this argument should have no more weight in respect to the etiology of paresis than it has to the causation of *tabes dorsalis*, which is equally unaffected by anti-syphilitic remedies. No one, so far as I know, claims that syphilitic gross lesions are characteristic of paresis; indeed, it is believed that they are very seldom, in a true sense, present, and that the rôle of syphilis is not so much the direct excitant of the *peri-encephalitis* as a powerful predisposing condition. So far as I am able to learn from personal clinical observation, and from the study of pathological researches made by competent investigators, it would appear that the profound debility of the vascular system produced by the invasion of the syphilitic elements, lays the foundation upon which, or out of which, under the varying stresses, etc., to which humanity is subject, the true lesions of paresis spring. This explains the failure of specific treatment to produce cures in any considerable number of cases, and is, one would think, in strict harmony with the chronological relation of paresis to the initial specific lesion.

As to prognosis, one is obliged to give a most unfavorable opinion. Still, it is possible that with a more accurate understanding of the very early symptoms of the disease, paresis may ultimately become less intractable with respect to treatment than it now, unfortunately, is at the period when it comes under observation.

HEMOPHILIA.¹

BY H. F. VICKERY, M.D.,

Physician to Out-Patients, Massachusetts General Hospital, and Instructor in Clinical Medicine, Harvard Medical School.

HEMOPHILIA is a congenital and usually hereditary tendency to obstinate hemorrhage, occurring either spontaneously or from seemingly inadequate mechanical injury. The disease is often further characterized by swelling of the joints.

Some cases have been found to develop in previously healthy families, but in general it can be said that the influence of heredity is very great. Dana made up a total of 770 cases of this rare condition in 256 families.

The manner of transmission is interesting. The females usually escape, there being but one female, it is said, to eleven male sufferers; but the women transmit the disease to their sons. If a male bleeder lives long enough to beget boys and girls, it is probable that none of them will be bleeders, nor the sons' sons, but the daughters' sons will exhibit the tendency. Legg reports one family where hemophilia has continued for two hundred years. At Tenna, in Switzerland, there were two unrelated families in which the disease had been known to exist for a century. In 1855 the females of these families renounced marriage for themselves, and in 1879 there was no longer a well-marked case of hemophilia in the village.

All authorities say that the women of bleeder families must not marry. A male bleeder ought not to do so, but a healthy male member of a hemophilic family has a fair chance for healthy descendants.

Pathological researches have not proved fruitful with regard to hemophilia. Occasionally thinness of the walls of the blood-vessels has been observed. Immermann and Winters found the superficial arte-

¹ Read at a meeting of the Clinical Section of the Suffolk District Medical Society, December 16, 1896.

ries large in proportion to those coming from the heart. Sir William Jenner held that there was "a tendency to plethora in the smaller vessels." Certain changes noted in the walls of the blood-vessels may be due to the malnutrition occasioned by anemia. The blood itself has been found normal in its corpuscular elements and its saline constituents. Before a hemorrhage there may be more than the normal number of red globules. Blood withdrawn for examination, while no bleeding is going on, will coagulate, but, as a rule, much slower than normal, for example, in forty-five minutes instead of five minutes.

Prof. A. E. Wright,² of Netley, says: "I have convinced myself by a somewhat extensive series of observations on the blood of hemophiliac families, that the blood of hemophiliac patients and of their female ascendants is characterized by a notable paucity of white-blood corpuscles, and especially by a relative paucity of the polynuclear white-blood corpuscles."

The swollen joints are due to the extravasation of blood either into the connective tissue surrounding the joints or into their synovial cavities. Occasionally there is also evidence of inflammation.

The disease is apt first to manifest itself when the child begins to walk, thus exposing himself to mechanical injury. The cutting of the umbilical cord has caused death in four cases, and vaccination in two (Grandidier). In women, menstruation and childbirth are seldom accompanied with special dangers—a rule to which there are exceptions. Grandidier is quoted by Osler as reporting fatal hemorrhages from the following wounds: blow on head; slight scratches on skin or abrasion of dermis; laceration of the frænum of the lips; bite of the tongue; fall on the mouth; blow on the nose; blow of a stone on the finger; cut in paring the nail; fall on the head, with meningeal hemorrhage (two cases, brothers); and rupture of the hymen on the wedding night. In hemophiliacs, leeching, extraction of the teeth and circumcision are very hazardous operations. Oscar Müller³ reports that a rather delicate new-born girl had a one-per-cent. solution of nitrate of silver put in the eyes and repeated after twelve hours, as a prophylaxis against ophthalmia. Soon after, there was much bleeding from both conjunctivæ, proving fatal after three days. Neither in life nor post-mortem was there detected any macroscopic injury or change in the membrane.

On the other hand, it is consoling to know that Bertrand and Pilcher⁴ both think that the dangers of capital operations in these cases have been exaggerated, because the larger arteries bleed no more than in ordinary patients.

Three hundred and thirty-four spontaneous hemorrhages, tabulated by Grandidier, were: epistaxis, 169; from the mouth, 43; stomach, 15; bowels, 36; lungs, 17; urethra, 16; and, in a few instances, bleeding from the skin of the head, the tongue, finger-tips, tear-papilla, eyelids, external ear, vulva, navel and scrotum.

The first hemorrhage is seldom fatal; but of 152 boy subjects, 81 died before the age of eight years. After adolescence there is a tendency to an amelioration of the condition.

The quantity of blood lost is sometimes enormous. For example, Fagge says that after the extraction of a tooth, half a gallon escaped in twenty-four hours. Epistaxis may destroy life in the same length of time.

With regard to treatment, it is evident that we should guard the patient against accidents, and should abstain if possible from any operative interference whatsoever. For the actual bleeding compression should be tried, combined with absolute bodily rest. It should be remembered, however, that excessive pressure is peculiarly apt in hemophiliacs to cause a slough. Perchloride of iron has proved itself one of the best local and internal styptics in these cases. The actual cantry has sometimes been of service. Iodoform and autipyrine are good local remedies.

Professor Wright⁵ has done some good work on the therapeutics of hemophilia. Briefly, he advises (1) the internal administration of chloride of calcium, of which the dose for an adult is fifteen grains three times a day; or thirty grains twice a day; (2) the local application of one-half of one-per-cent. aqueous solution of chloride of calcium, which may be mixed into a paste with finely powdered chalk; (3) the inhalation of carbonic dioxide gas; and (4) its local exhibition for either epistaxis or menorrhagia or hemoptysis. The stream of gas should be gentle at first, till the mucous membranes have been soothed by it. Also (5) the local application of cell-nucleo-albumin, which may be obtained from a thymus gland or a testicle or even a piece of gastric mucous membrane, mincing it up and extracting its virtues by means of slightly alkaline water.

Apropos of the medical use of chloride of calcium, Professor Wright confirms the observation of Dr. Wickham Legg, that hemophiliac children are often addicted to eating lime and plaster; but he also states that the long-continued or immoderate use of calcium chloride defeats its own object, rendering the blood less coagulable than at first. The ingestion of alcohol, lime-juice and lemon-juice he finds injurious to bleeders—likewise the inhalation of oxygen; yet the carbonic dioxide gas, when inhaled, should be freely mixed with ordinary air, as asphyxia aggravates the bleeding.

Daland and Robinson⁶ published a case in which the application of a four-per-cent. solution of cocaine was useful. They observed an increase in the frequency and violence of the hemorrhages in their patient upon his removal from a height of 1,800 feet to one of 2,200 feet above the sea. A dry and warm climate is favorable for hemophiliacs.

Dr. Olivier⁷ reports the occurrence of severe menorrhagia upon the first menstruation of a girl, age thirteen, who had suffered from hemophilia since childhood. He expressed anxiety as to the future and begged for suggestions from his colleagues; but he had formulated for himself the following line of treatment:

- (1) Injections of hot water every two hours.
- (2) If necessary, the intra uterine application of the galvano-cautery (50 milliampères) followed by packing of the vagina.
- (3) General hygienic treatment.
- (4) Hydrastinine hourly during hemorrhage.

The present writer's personal experience has been

limited to three cases. One was a boy, H. G., whose sister and two brothers were healthy and in whom heredity could not be traced. He was rather delicate in appearance, of slight build and with rosy cheeks. His person was never free from ecchymoses, and he occasionally had severe epistaxis—a particularly copious flow during an attack of typhoid fever causing a fall of temperature and other symptoms of collapse. When about fourteen years old, while in swimming, he attempted to dive and struck the water too horizontally, so that he experienced a severe shock. Soon after he began to have a severe neuralgia of the trigeminal nerve and paralysis of a cranial nerve or its branches—the exact notes have been mislaid—and Dr. Geo. L. Walton, who saw the case in consultation, agreed with me that probably a hemorrhage had taken place inside the cranium. The termination was favorable; and the boy has now become quite a robust young man.

A second case was one of menorrhagia in a girl, age twenty-four, who had been subject since childhood to purpuric spots on the arms and legs and to severe epistaxis. In this case again no family diathesis was known. It was reported in the *Boston Medical and Surgical Journal*, November 27, 1890.

The third case, N. O., also had no family history of hemophilia. Her mother's mother had three blue babies who died young. The patient was cyanotic when born, and for three months was regarded as a blue baby, but thereafter her complexion became clear. Until she was four years old she had no natural hair but merely lanugo. While a little baby, she had some bloody fecal discharges, and the pressure of the hands in lifting her would leave black-and-blue spots. Twice when milk teeth were extracted she had serious bleeding. A blow on the leg caused a large hematoma. Her mother had sometimes to get up in the night and change her night-dress and the bed-sheets because of bleeding from mosquito bites. There was never any arthritis.

She first menstruated at the age of thirteen, but scantily. Three weeks later, there was a slight show of blood; and a week after that a profuse and obstinate menorrhagia began, causing great exhaustion. Finally, Dr. W. H. Richardson and Dr. C. W. Townsend were called in by the family physician, Dr. G. W. Tinkham, of Weymouth. The flow had then lasted twelve days; the pulse was 140, and a moderate amount of pale watery blood was leaking through the tampon which had been inserted the day before. The tampon was safely removed two days later. A slight oozing, however, continued for six days more. An interesting account of this experience was given by Dr. Townsend in the *Boston Medical and Surgical Journal* of November 27, 1890.

From that time till her death in January, 1896, this young lady suffered from menorrhagia. On three occasions only were so few as thirty-six napkins used. More often one hundred were needed, and sometimes two hundred. After the bleeding ceased, she would lie one or two weeks in bed, to recuperate, and then would gain color and strength very rapidly; so that after she had been downstairs three or four days she would have so brilliant a color that it was difficult to believe she could have been ill.

The last hemorrhage continued some four months. The patient had complained during some time of pain in the region of the heart, but nothing could be made

out except weakness of that organ, which was naturally ascribed to the profound anemia. The writer was not called to see her till near her end, and did not venture to inaugurate any energetic treatment, for which caution the findings of the pathologist, Dr. Whitney, make him thankful. Hot douches had not proved efficient. Tamponing had once been followed by such septic symptoms that Dr. Tinkham did not feel authorized to repeat it. The autopsy will be reported by Dr. Whitney.

ON THE VALUE OF PROMPT CO-OPERATION WITH THE MUNICIPAL AUTHORITIES FOR THE PREVENTION OF THE SPREAD OF DIPHTHERIA.¹

BY ROBERT W. GREENLEAF, A.M., M.D.

As diphtheria has been so prevalent of late, particularly in our suburban towns, the following cases are of interest. They illustrate what can be done to prevent the spread of this disease when physicians in private practice avail themselves of such measures as those now so efficiently carried out in our City Hospital.

One focus of contagion was as follows: On November 10, 1896, a woman came to my office and asked me to see her little girl, Annie M., seven years of age, about whom she was anxious, as the child complained of sore throat. She had been playing about on that day, but had not been as well as usual for two days.

She lived in another part of the city, was not considered to be very ill, and, as it was already nine o'clock, one might have felt justified in satisfying the mother with temporary measures and postponing his visit till morning. As diphtheria was possible, the visit was made at once. A membrane characteristic of the disease was found in the throat. The glands of the neck were considerably swollen, and the diagnosis, diphtheria of a septic type, was made.

The problem of the household was a serious one. The child had contracted the disease at school. Three younger children, aged respectively five, three and one years, were still well. They, with their mother and father, were crowded together in a tenement, consisting of a kitchen, bedroom and two cold "side-rooms." Could the disease be arrested then and there? I advised immediate isolation and disinfection.

The husband went with me to the City Hospital. Admission was at once secured, and the ambulance sent for the patient, who arrived safely soon after ten o'clock. Notification to the Board of Health that night ensured disinfection of the rooms next morning.

Two days later matters stood in this way: A visit to the hospital found Annie much improved and the membrane disappearing under the antitoxin treatment. The children at home had had their throats cleansed several times a day with a solution of peroxide of hydrogen. All were well except the baby, who was a little irritable. Diphtheria was suspected, but on the next day she was rather better. On the following day, however, she had a characteristic membrane on the tonsil, a culture from which confirmed the diagnosis of diphtheria. The other members of

¹ Read before the Clinical Section of the Suffolk District Medical Society, December 16, 1897.

the household were not affected. The problems then were, Shall the mother accompany a nursing child to the hospital, and leave an infected household to the care of friends who would thus be likely to still further spread the disease by exposing their own children? or would it not be better to let them remain at home? The latter plan was decided upon. The baby was given a full dose of antitoxin, and the other children were given immunizing doses.

At my visit on the 20th, ten days from the appearance of the first case, matters stood thus: The baby was entirely free from any symptoms, and was playing about the room as well as usual. No one else in the household had been ill, and no untoward symptoms had arisen from the antitoxin treatment. The place had been fumigated a second time by the Board of Health on the day before, and a note had just come from the hospital directing the parents to take the child home that afternoon. Certainly a very happy result and markedly in contrast to those of the pre-antitoxin days, when with one case in a family of children the chances were that all would have taken the disease and that one or more would have succumbed.

Another starting-point of infection was as follows: On the evening of November 16th I was called to attend a servant in one of our leading hotels. She was in a room containing about a dozen beds, some of which were occupied by two persons. She had an extensive, foul-smelling, diphtheritic membrane in her throat. That day she had been away, and had just come back to go to bed. She had felt ill only two days. In this case also, permission having been given by telephoning the proper authorities, she was sent at once to the City Hospital. The girl who had slept with her the preceding night, though well, was also sent there for observation and extra security. The bed-clothing was disinfected by boiling water and the mattress burned. Two other maids who felt ill were examined. One had a slight coryza, another had a pharyngitis. Their throats were cleansed with peroxide and they were in good condition the next day. No other cases of diphtheria have occurred since, both maids sent to the hospital are now well; and one may justly feel that a contagious conflagration was averted among the servants and guests of the house.

Another focus was equally instructive. In mid-summer I was called by Dr. D. W. Cheever to aid him in the care of a young girl suffering with tonsillar abscess, by making visits in his absence. Her case was somewhat doubtful as she had a considerable and foul exudation. A culture proved it to be non-diphtheritic. At the same time a servant in the house was just beginning to complain of sore throat. Certain signs suggested diphtheria. Immediate removal to the hospital was advised and carried out. Cultures confirmed the diagnosis, and she finally recovered under the antitoxin treatment.

In this case, had the girl remained in the house, it might have proved a serious matter. Several seamstresses were employed there; and, had illness come among them, not only would it have proved destructive to the business of a hard-working and deserving woman, but each case would have been a fresh distributing centre for the disease. As it was, no other cases resulted.

In offering these cases which show so strikingly the value of prompt isolative measures and of the anti-

toxin treatment, I desire to express my appreciation of the admirable contagious service at the Boston City Hospital; also my indebtedness to the resident physician for the privilege of inspecting it.

To those of us who were almost literally bathed in diphtheria, scarlet fever and the like during our hospital life in the pre-antitoxin days the improved conditions are most welcome.

A word as to what I saw there (when I visited the hospital for information concerning the little patient first mentioned in this paper) may be of interest to those who have not had the opportunity of making such a visit.

Dressed in the ward cap and gown and carefully disinfected at the close of the visit, the likelihood of my carrying contagion elsewhere was minimized.

Instead of our old wards, though they were as neat and clean as careful oversight could make them, all was in the perfection of modern ward construction and appliances.

Instead of signs of suffering in the little patients, with which we were only too familiar, of the 92 cases of diphtheria seen that evening, all appeared sleeping peacefully. Intubation had replaced tracheotomy. There were ten intubated cases present; all doing well. There was not a sound of noisy breathing or coughing in either ward, nor was there a particle of odor once so characteristic and dreaded in this disease. The floors were so clean that the hand or a piece of white cloth could be rubbed over them without being perceptibly soiled.

Results in the pre-antitoxin days showed a mortality of 43 per cent. counting all cases, and 35 per cent. in selected ones. The present figures show a mortality of 13 per cent. for all cases and about 8.5 per cent. in similarly selected ones, that is, excluding moribunds and late-entering cases. This is a just exclusion if both percentages are stated, as such cases are hardly fair exponents of the value of hospital care. Since the introduction of the antitoxin treatment I am told that there have been 1,972 cases treated up to October, 1896. Of these, 70 cases have died within twenty-four hours. Of 200 cases of intubation the mortality had been but 53 per cent., whereas the usual rate previously was 72 per cent. for intubation and 88 per cent. for tracheotomy.

These splendid results are largely due to the antitoxin treatment. There have been no ill results worthy of mention attending its use. It has been shown to be competent in the prophylaxis of exposed patients. Certainly, sufficient data are now accumulated to permit of its unhesitating acceptance as a boon of inestimable value.

It is but fair, however, to consider that some of the success so strikingly evident at the Boston City Hospital was due to the scrupulous care in every detail of ward administration, including the foresight in providing the best appliances for ventilation, for disinfection of clothing, for cremation of ward garbage, dust and the like. Credit must also be given in part to the judicious treatment often associated with the antitoxin, supportive or stimulant in character.

A knowledge of how admirably appointed and how efficiently managed this service is should certainly be widespread in the community. The profession and the laity should be fully aware that by prompt and judicious co-operation with the authorities much can be done to minimize the risk of spreading diphtheria.

THE HOME MODIFICATION OF MILK.¹

BY J. L. MORSE, M.D.

I MERELY wish to make a few additions and corrections, based on my experience of the last summer, to the paper which I read before this Section last spring on the home modification of milk.²

The bottles which I recommended at that time for use in the home modification of milk were those provided by the Walker-Gordon Laboratory at a cost of ten cents apiece or a dollar a dozen. This item for bottles made up considerably more than half the first cost for apparatus. During the summer I received many complaints from patients of the fragility of these bottles; that many of them broke during the process of Pasteurization, that many more broke while heating, and that they almost invariably broke if dropped. As the large initial expense and the expense from breakage was quite an important item to the poor people I looked about to see if I could not find a cheaper and stronger bottle. I found two which are fairly satisfactory. One is that made by Whitehall & Tatum for the Arnold Sterilizer. They retail for five cents apiece or forty cents a dozen for the large size and thirty-four cents a dozen for the small size. These bottles are not quite as large as the Walker-Gordon bottles of corresponding size, and have a smaller neck, which makes them harder to clean; but, on the other hand, are much stronger. It is only fair to say that Whitehall & Tatum make the bottles for the Walker-Gordon Laboratory. The other is a triangular bottle, known as the "Three Star Nurser," which can be bought at Weeks & Potter's for five cents apiece or thirty-eight cents a dozen. This bottle is stronger, and is accurate, but has the disadvantage of a small neck and a broad bottom which render it more difficult to clean. This bottle is, as far as a glass bottle can be, indestructible, and consequently is the most economical. Using either of these bottles reduces the first cost for the apparatus to about \$1.25. The lowest terms I could make before were about \$1.80.

Another summer's experience in out-patient practice with this method for the home modification of milk has only served to confirm me in my previous opinion that home modification is feasible and satisfactory for poor people. The only difficulty I have met with has been in inducing them to undertake it. They are often frightened when told about the process, but I have never yet had a person give it up who once tried it. They all say that it is very little trouble after the first week or two, and that they do not mind it. It does not take them over an hour a day.

I also wish to call attention to the article by Freeman, of New York, read at the meeting of the American Pediatric Society last May. He showed that Pasteurization for thirty minutes at 65° C. is sufficient to destroy pathogenic organisms, and does not cause the same chemical changes which Pasteurization at a higher temperature does. The principle of his apparatus is that a definite amount of boiling water will in a certain period of time raise a certain other definite amount of cold water and cold milk to the temperature of 65° or 66° and keep it so half an

hour. His apparatus is a tin pail in which a certain amount of boiling water is placed, and a case or stand composed of metal cylinders, each of which contains a bottle surrounded with cold water. The pail is partially filled with boiling water, the cylinders placed in it and covered up for three-quarters of an hour. The first fifteen minutes raises the temperature of the milk to 66° and a temperature of 65°-66° is maintained for half an hour more. The hot water is then replaced by cold and the milk set on the ice. The cost of this apparatus is \$3.50 for the cheapest and \$6.00 for the more expensive, which places it somewhat beyond the use of poor people. It may be obtained of J. S. Dougherty, 411 West Fifty-ninth Street, New York.

Clinical Department.

A CASE OF SEPTICEMIA OF OBSCURE ORIGIN.¹

BY JAMES J. MINOT, M.D.,

Visiting Physician, Carney Hospital; Physician to Out-Patients, Massachusetts General Hospital; Visiting Physician, Long Island Hospital.

MRS. K., thirty-five years old, entered the Carney Hospital November 19, 1896. She lived in a district known to be malarial. She had always been well. Had had five children, no miscarriages. Catamenia always regular, and last one three weeks ago. Her present trouble began, two weeks before entrance, with a chill without previous symptoms. The chill has been repeated at frequent but irregular intervals since. On some days there would be one, some two, some three, and again no chill. For nine days there had been considerable diarrhea. For three days there had been a good deal of pain in the left shoulder.

On entrance her temperature was 103°, pulse 140, respiration 30. She was evidently very sick; the face was dusky. Nothing abnormal found about the head, eyes, mouth, lungs or heart. The abdomen was very lax and not tender. The area of splenic dulness was somewhat increased, but the spleen could not be felt. There was a mass below the ribs on the right, which felt like and was considered to be the lower edge of the liver, with below this what was thought to be the lower part of a misplaced kidney. It was hard, not tender, with the liver edge distinctly felt. No rose-spots or other eruption anywhere. By vagina the uterus was found to be large, firm and not tender. There was nothing abnormal felt in the pelvis, and no tenderness there. No vaginal discharge. The urine contained one-tenth per cent. albumin; a few pus cells and one granular cast were found. There was marked tenderness over the anterior part of the left shoulder, but no pain on motion, and no heat or redness there. Blood examination showed 6,000 white, no plasmodium.

There was a chill that night, another the next day, and two on the third day, with a third rise of temperature but no chill. At no time throughout the course of the case did the temperature go as low as 99°.

On the third day there was much pain and tenderness in the calf of the right leg.

On the fourth day there was pain and tenderness in the right abdomen, but nothing could be felt there. This, the pain in the calf and the shoulder gradually

¹ Read before the Clinical Section of the Suffolk District Medical Society, December 16, 1896.

² Boston Medical and Surgical Journal of June 4, 1896.

¹ Read before the Clinical Section of the Suffolk District Medical Society, December 16, 1896.

disappeared in a few days. The blood examination showed now 12,000 white. The patient was thought to have septicemia from the first; but no evidence as to the source of the infection could be found. The question of exploratory laparotomy was considered frequently, but with no good reason for supposing the original trouble to be intra-abdominal, and with the patient in such poor general condition the surgeon was unwilling to undertake it.

On the fifth day there was thought to have been plasmodium found in the blood. The blood was frequently examined by different observers but plasmodium was not again found; but it was admitted by several that the slides taken on the fifth day probably did show some. On the fifth day there were 17,000 white. There had been no distinct chill for two days but irregular rises in temperature, with sweating. The patient had been given strychnia, whiskey and quinine. She was now given quinine in fifteen-grain doses, until cinchonized, but with no result.

On the sixth day the serum reaction for typhoid fever was said to be present, but subsequent examinations failed to confirm this.

On the seventh day the spleen could be felt, and it increased in size until death occurred on the ninth day after entrance to the hospital,—three weeks after the first symptom, the initial chill.

From the fifth day to the end there were only three chills, but a very irregular temperature. The diarrhea ceased a day or two after entrance, and began again a few days before death. From time to time new points of pain and tenderness appeared, but soon disappeared again. At no time was there pain or tenderness over the uterus or pelvis. The patient was delirious the last three days, and passed her urine involuntarily. The day before she died moist râles appeared in both lungs at the back.

The diagnosis was septicemia, possibly following an unrecognized typhoid and perhaps also malaria.

The autopsy was made by Dr. J. J. Curry. It showed the peritoneum to be slightly infected, especially on the left side of the pelvis; and the mesenteric and retro-peritoneal glands moderately enlarged and red.

The tumor felt in the right side of the abdomen was a greatly elongated and curiously shaped right lobe of the liver.

The lungs were edematous, with several small, shot-like areas of consolidation scattered through both lower lobes.

The liver showed fatty degeneration, and was considerably enlarged.

The spleen was greatly enlarged; light purplish color; capsule thin and smooth; old infarction on upper edge; on section, the pulp very soft and of purplish-red color.

The kidneys showed a cloudy swelling.

The Peyer's patches and the solitary follicles of the intestines were much swollen, but nowhere in small or large intestines were there any signs of either old or fresh ulcerations to be found.

The uterus was considerably larger than normal; its cavity was enlarged and contained about half a drachm of necrotic-looking material. Both ovaries firm, and on section appeared to consist mainly of fibrous tissue, a corpus luteum was found in the right ovary. In the left broad ligament the ovarian vein was dilated considerably and filled with pus. The

peritoneum about this area was injected but there was no exudation in it.

The iliac and femoral veins did not contain any thrombi.

In the left sterno-clavicular joint there was a small quantity of thin creamy pus. Both shoulder-joints normal.

No other foci of pus than those described could be found.

The axillary and inguinal glands were large and red.

The brain showed nothing abnormal.

Anatomical Diagnosis: Typhoid (?); acute splenic tumor; broncho-pneumonia and edema of lungs; general acute lymphatic hyperplasia; purulent arthritis (sterno-clavicular); purulent phlebitis (left ovarian vein); fatty degeneration of liver; cloudy swelling of kidneys; white infarction of spleen; enlargement of uterus, with endometritis.

Bacteriological Examination: Cover-slip preparation from pus of sterno-clavicular joint and of ovarian vein, made at time of autopsy, showed numerous chains of streptococci. Cultures from lung, liver, kidney and spleen showed abundant growth of streptococci. The culture from spleen contained pure growth of streptococci. Cultures from lung, liver and kidney showed, in addition, a few large, moist colonies, which, when grown on the various media used to differentiate colon and typhoid bacillus, proved to be colon bacilli, that is, they coagulated and acidulated milk, developed gas in sugar agar, gave indol reaction in Dunham's peptone solution, and showed profuse growth on potato.

Bacteriological Diagnosis: General infection with the streptococcus pyogenes.

Notwithstanding the post-mortem examination the true original source of the infection seems to be unsolved. From the autopsy the question of an abortion would have to be seriously considered; subsequent questioning of friends gave no reason to suppose this had happened.

A CASE OF PRECOCIOUS MATURITY.¹

BY CHARLES W. TOWNSEND, M.D.

THE subject of this note was brought to my clinic at the Children's Hospital on December 7, 1896, when nearly a year old, having been born December 20, 1895. The mother and father are both well, and there is one brother and sister whose condition is normal. The father was born in North Carolina, the mother in Nova Scotia. There is no history of precocious menstruation in the family.

The child weighed nine pounds at birth, was breast fed, and for the last few months has had milk and some cereal. At four months she cut her first tooth, and now has seven incisors. At the age of three months the mother noticed that the breasts were enlarging, and at six months the child apparently menstruated for four days. Every month since then the child has had a bloody discharge from the vagina for from two to three days, amounting to several teaspoonfuls of blood. The child becomes heavy and dull for a day or two before the flow appears, and seems relieved and bright as soon as it is established. There has been a slight growth of hair about the vulva in the last few months.

¹ Read before the Obstetrical Society of Boston, January 19, 1897.

The child has always been well and the family have noticed no mental precocity.

Physical Examination.—A fat, healthy, placid-looking child. Breasts noticeably enlarged; areolæ not pigmented but prominent; nipples not developed; glandular tissue present in both breasts. Straight, downy, light-colored hairs on mons veneris, a quarter-of-an-inch long. Vulva not abnormal in appearance, except that hymen has a large opening. Height of

child, thirty inches; weight, twenty-eight pounds. The child showed no evidence of modesty on being examined.

On January 11, 1897, I saw the child at its home, and found it to be menstruating, the flow having started that day. About half a teaspoonful of blood was on the clothing, and a little was to be seen inside the vulva. The accompanying photograph shows the development of the breasts.

ABSTRACT OF PAPER BY DR. J. L. MORSE ON PRECOCIOUS MATURITY.

The genital hemorrhages of little girls may be divided into four classes:

- (1) Genital hemorrhage of the new-born.

- (2) Hemorrhages due to tumors of the genital organs.

- (3) Precocious menstruation.

- (4) Precocious maturity.

The genital hemorrhages of the new-born have nothing in common with menstruation, but are due to some local catarrhal condition or to pelvic congestion.

Certain tumors may give rise to uterine hemorrhage at irregular intervals and to premature development of the genital organs with hypertrophy of the breasts.

Thirty cases of precocious menstruation have been reported, the incidence being almost equally distributed through the first seven years of life. The flow was usually regular, lasted from one to five days, was usually preceded by moulmina and persisted for a variable time. It apparently had no influence on the general health, and was unaccompanied by premature development of the body or genital organs.

Puberty manifests itself by an *ensemble* of symptoms which appear in a variable order. Precocious maturity is the condition in which this *ensemble* of symptoms develops prematurely. Some signs of the condition are always present at birth. Menstruation is never the first symptom, but often the first to call attention to the condition. About sixty cases have been reported. Menstruation began most often in the first two years. In those which were followed it continued as long as when it begins at the usual time. In the only satisfactory autopsy evidences of ovulation were present. Three became pregnant at about eight years. Sexual desire was often present very early. The mental development was not as rapid as the physical and sexual.

Precocious maturity is a physiological anomaly of development. Nothing is known as to its etiology. There is no medical treatment for the condition. The psychological treatment, however, is important. The sexual precocity of these unfortunates must be hidden and their sense of modesty respected. They must be carefully guarded against voluntary or involuntary intercourse.

The following typical case of this unusual condition was observed by the writer:

Louisa J., weighed fourteen pounds at her birth. She presented an undue development of the breasts, and had a little hair on the pubes. She began to menstruate at nine months, and has continued to flow regularly up to the present time, a period of six months. At fourteen months her appearance was that of a child of three years, her weight 36 pounds, and her height 32½ inches. Her intelligence was above normal. She manifested no unusual modesty or evidence of sexual desire. There was a moderate growth of hair in the axillæ, down the back and about the genitals. The breasts each contained a mass of gland tissue as large as a pigeon's egg. The nipples were well developed and the areolæ of dark pink. The external genitals corresponded in development to those of a girl of seven or eight. The vagina was easily distensible, four centimetres in depth, one and one-quarter centimetres in width, and contained rugæ. There was no history of early menstruation in either family.

DISCUSSION.

Dr. W. L. BURRAGE said that he was fortunate in having an opportunity to examine digitally Dr. Morse's case. The introitus and vagina were remarkably large for an infant and the cervix and uterus could be plainly made out. Without ether it was, of course, impossible to distinguish the ovaries.

Dr. J. R. CHADWICK referred to the extreme rarity of this anomaly and also to the absence of any ascertainable cause.

Dr. C. W. TOWNSEND said that we not infrequently see reported in medical journals cases, where bleeding from the vagina occurs during the first few days of life, this being spoken of as menstruation. He believes this is not at all rare, having seen it a number of times in both hospital and private practice. It is quite distinct from the cases reported to-night, as it does not recur and is not associated with any developmental changes. It is of no significance.

Medical Progress.

PROGRESS IN PATHOLOGY.

BY JAMES HOMER WRIGHT, M.D.,

Director of the Laboratory of the Massachusetts General Hospital.

THE EFFECT OF THE BACILLUS OF INFLUENZA UPON THE CENTRAL NERVOUS SYSTEM.¹

A. CANTANI, JR., has subjected this question to a most thorough experimental study. Bearing in mind the fact that the effect of the influenza infection in man is very marked in the central nervous system, he was led to study the effect of the intra-cranial inoculation of rabbits with this organism.

Such inoculation with virulent culture, by trepanation, he has found to produce severe nervous symptoms, high temperature and death in twenty-four hours.

At the autopsy there was often observed at the site of the wound, an edema, containing numerous influenza bacilli and spots of blood. The meninges were always hyperemic, infiltrated with a hemorrhagic exudate and clouded. The brain was markedly hyperemic, the ventricles often containing a purulent exudate in which were numerous influenza bacilli. On section, the substance of the brain appeared usually beset with ecchymoses, and microscopically contained numerous bacilli along with numerous polynuclear leucocytes. In short, the condition was that of an acute encephalitis. The bacteria seemed to spread preferably by the lymphatic channels. To a certain extent the spinal cord was also invaded by the bacilli, apparently by way of the central canal. In sections of the cord there were some hemorrhages to be seen, and in places numerous leucocytes; but, in general, the process was not as severe in the cord as in the brain. The lesions elsewhere most frequently noted were as follows: Bloody serous exudate in the peritoneal cavity, acute congestion of the spleen, hyperemia of the kidneys, hemorrhages into the adrenals, and incipient fatty degeneration of the liver. The lungs were always injected, and in the pericardium there was often an accumulation of clear fluid.

Control experiments of various kinds seemed to show that these results of the inoculation of the influenza bacillus in this manner are peculiar to that organism. The most interesting fact, however, brought out by this investigation, was that practically the same effects as those above detailed might be produced by inserting beneath the dura mater of the animal a few milligrammes of the dead growth of the bacteria which had been previously killed by heat. This result is another confirmation of the idea that the effects produced by the influenza infection is due to a poison closely associated with the bodies of the bacilli themselves.

The investigation must be regarded as a considerable contribution to our knowledge of the influenza organism, in view of the fact that hitherto there has been little experimental evidence of its pathogenic power.

THE TOXINS OF DIPHTHERIA.²

The isolation of the poisonous substance formed in cultures of the diphtheria bacillus, free from all proteid impurities, is claimed to have been at last accomplished by Brieger and Boer.

The bacillus was cultivated upon large quantities of dialyzed human urine; and from this culture fluid there was obtained a small quantity of a substance, barely visible on the filter, which gave no proteid reactions, was optically inactive, was easily destroyed by alcohol, ether, acetone, acids and oxidizing agents, but was only slightly affected by weak alkalies and reducing agents. This substance, by its effect upon animals, showed itself to be identical with the toxin contained in the filtrate of the usual bouillon cultures.

From the bodies of the bacilli themselves, after the removal of all the "toxin" contained in them, the authors have obtained another poisonous material, which is to be regarded as of a different nature from that of the toxin. Ten milligrammes of this substance, when dried, powdered and injected in watery suspension beneath the skin of a guinea-pig, causes the death of the animal, with necrosis and suppuration at the point of inoculation, within forty-eight hours. The lesions of the viscera, however, which are so characteristic of poisoning with the toxin, are not produced.

The substance is insoluble, is not especially affected by boiling in water, and when heated with sodium hydrate gives off gases with odors resembling those of the ptomaines cadaverin and putrescin.

THE VIRULENCE OF THE BACILLUS IN MILD CASES OF DIPHTHERIA.³

In some localities there still seems to remain a deeply-rooted belief among medical men, that only those cases of acute angina which present a pseudomembrane are to be regarded as diphtheria, and are to be isolated and treated as such, notwithstanding the large amount of evidence to the contrary. It seems also to be commonly believed that the bacilli in mild infections, which appear as tonsillitis or pharyngitis, have only a low grade of virulence, which is a false idea.

With the purpose of doing something towards correcting these erroneous views, Dr. H. M. Biggs, of the New York Board of Health, reports 19 cases, which were clinically follicular tonsillitis or pharyngitis throughout the duration of the disease (with late laryngeal symptoms in two), from which the bacillus diphtheriae was isolated and its virulence tested on guinea-pigs. The results showed that the bacilli from 17 of the 19 cases were fully virulent for the animals, which is in agreement with the observations of others.

The author emphasizes the importance, from a sanitary standpoint, of considering these cases as true diphtheria.

DIPHTHERIA BACILLI WITHOUT DIPHTHERIA.⁴

E. Müller has made cultures from the throats of all children who entered the children's division of the Charité in Berlin, with reference to the occurrence of diphtheria bacilli.

Among 92 children examined, 20 were found in whose throats diphtheria bacilli could be demonstrated, although no inflammation of the parts was present. In six of these children the bacilli were present on the day of their entrance, while the remaining 14 became infected during their stay in the hospital. In one of the cases full virulent bacilli could be demon-

¹ Zeitschrift f. Hygiene u. Infect. Krank., Bd. xxiii, 1896.

² Deutsche med. Woch., December 3, 1896.

³ American Journal Medical Sciences, October, 1896.

⁴ Jahrbuch für Kinderheilkunde, Bd. xliii, Hft. 1.

strated during two months and a half, without any symptoms referable to their presence. In this connection, however, it should be stated, that all of the children were treated with prophylactic antitoxin injections.

On the ground of the frequency of the occurrence of infection with the diphtheria bacillus without symptoms, as shown by this investigation, the author explains the frequency of the occurrence of endemic diphtheria cases which had been observed in the children's division of the hospital. The absence of symptoms in these cases he explains upon the hypothesis that a personal immunity exists.

The virulence of twelve of the cultures was tested upon guinea-pigs. Six of them showed themselves characteristically virulent, while in the remaining six a lack of virulence was shown, only local reaction at the point of inoculation and, in some instances, emaciation being observed.

THE SERUM-REACTION IN THE DIAGNOSIS OF TYPHOID FEVER.⁵

Wyatt Johnston and D. D. McTaggart sum up the results of their examination of the blood-serum of over 500 patients with reference to the presence or absence of the "clump-reaction," that is, the property which the blood serum of typhoid fever cases has of causing typhoid bacilli to lose their motility and to aggregate in "clumps," or "agglutinate," when a small portion of it is mixed with a fluid containing the living bacilli in suspension.

Out of 129 cases, which were regarded as typhoid fever, if a few cases be excluded when the examination was made at an early stage or late in convalescence, but one apparently genuine case of severe typhoid fever was met with, which, when examined under satisfactory conditions did not give a decided reaction from the dried blood. Occasionally the first appearance of the reaction was delayed beyond the first week. They have never met with a well-marked reaction in any of the 500 cases, where there were not strong reasons for believing typhoid fever to be present. In the few cases where the result of the examination was doubtful, the mild type of the fever made an accurate clinical diagnosis impossible. In these cases the authors believe a bacteriological examination of the stools or of the spleen (by puncture with a hypodermic syringe) to be the most exact method of procedure.

In regard to the relative value of the dried blood as compared with the fresh serum, they report that they have not yet encountered a case of typhoid fever where a decided reaction was obtained with the latter and not with the former. The reaction, though specific in degree, is now generally considered to be quantitative; and small amounts of the agglutinative substances are admitted to be present in varying amounts in bloods other than those of typhoid fever cases. These specific substances, however, are an hundred-fold more abundant in typhoid blood.

It is the experience of the authors that the use of fresh cultures in bouillon, from stock cultures which have been under cultivation for some time, grown at room temperature, and transplanted at intervals of about one month, are the best to use, for the reason that the bacilli of such cultures seem to be much less sensitive to the small amounts of agglutinative sub-

stances which may be fortuitously present, than bacilli from cultures which have been made active by frequent transplantation and cultivation in the incubator. In this way false reactions may be avoided. They have also found that the dried blood is more potent than the fresh serum in causing the clumping, but not so potent in causing the stoppage of motility. Thus a decided agglutination can be obtained from weak solutions of the dried blood, when none is produced by stronger solutions of the serum.

Owing to this greater potency of the solution of the dried blood, there is a greater tendency to false reactions when active, virulent cultures are used, than is the case with the serum. This difficulty, however, is completely obviated by employing the attenuated cultures for testing purposes. Bacilli, which exhibit darting movements in the "hanging drop" are too sensitive for the test with the dried blood.

The authors also contribute some observations on serum reactions with the colon bacillus in supposed infections with that organism. They state that they have observed "colon reactions" in four cases having a step-ladder temperature curve and other symptoms suggestive of typhoid fever, and also in the one case of apparently true typhoid, which gave no reaction with the typhoid bacillus.

"Colon reactions" in typhoid fever, were found to be rare, even in cases where perforative appendicitis had occurred, provided the "typhoid reaction" was well marked.

THE BACTERIOLOGICAL DIAGNOSIS OF TYPHOID FEVER.⁶

Capaldi reports that he has several times isolated the bacilli from the stools with the aid of a special culture medium upon which their growth is characteristic. This medium has the following composition: water 1,000 c. cm., Witte's pepton 20 gm., gelatin 10 gm., glucose 10 gm., sodium chloride 5 gm., potassium chloride 5 gm., agar-agar 20 gm., and normal sodium-hydrate solution 10 c. cm. For the further proof of the identity of the typhoid bacillus, and to distinguish it from the bacillus coli communis, he inoculated from suspicious colonies two special forms of culture media. On one of these, which he calls Medium I, the typhoid bacillus will not grow while the colon bacillus does. On Medium II both species thrive. But the colon bacillus produces an acid reaction in it, while the typhoid bacillus does not. He claims that the use of these two forms of media is entirely sufficient for the determination of the identity of the typhoid bacillus, provided the microscopical examination shows the bacteria in question to have the usual shape and size of that organism. This statement he considered to be confirmed by the results of a very thorough and systematic study of the subject by himself and Professor Proskauer carried out in the Institute for Infectious Diseases in Berlin.

THE UBIQUITY OF THE BACILLUS OF TYPHOID FEVER.⁷

With the aid of the recently devised culture medium of Elsner, upon which the typhoid bacillus grows fairly characteristically, Remlinger and Schneider have made examinations of various potable waters, of soils and dusts from various sources, and of the intestinal discharges, for the presence of this organism.

⁵ Montreal Medical Journal, March, 1897.

⁶ Zeitschrift f. Hygiene u. infect. Krankh., Bd. xxiii, 1896.

⁷ Annales de l'Inst. Pasteur, No. 1, 1897.

Their results seem to show that the typhoid organism is more widely distributed and of more common occurrence than has hitherto been demonstrated.

Thirty-seven samples of drinking-water were tested and in nine of them bacilli, identical with the typhoid bacillus were found. Two of these samples came from districts in which an epidemic of typhoid fever prevailed; six came from towns where typhoid fever had existed.

With reference to their occurrence in the soil and dust, thirty samples from various places, were examined, and from seven of these the bacillus was isolated. Three of these were dust from inhabited rooms, while the remaining four were samples of soil from various depths down to one metre, taken in the neighborhood of dwelling-houses.

The isolation of the bacillus from the stools of hospital patients, with affections having no apparent relation with typhoid fever, was effected in five out of ten cases.

The bacilli thus obtained from these various sources were rigorously subjected to all the tests at present known for the recognition of the typhoid bacillus and found to conform to all of them, including the recently discovered "serum reaction." The identification of these bacilli as typhoid bacilli must therefore be accepted as justified, in the light of our present knowledge.

PRIMARY CARCINOMA OF THE LUNG.⁸

Hans Pässler has carefully studied four cases of this unusual form of pulmonary disease, and presents an interesting analysis of 70 cases, most of them well authenticated, which he has found in the literature. According to him, clinically, two groups of primary carcinoma of the lungs may be distinguished, depending upon the anatomical situation of the disease. Both groups have in common cachexia, metastases, cough and expectoration. Peculiar pains are rare.

The first group comprises those in which the growth is situated along the course of the bronchi at some distance from the root of the lung. These cases often run a course for a long time like a chronic tuberculosis. Later there usually occur complications in the form of bronchiectasis, pneumonia, and gangrenous processes.

The other group of cases comprises those in which the carcinoma develops at the root of the lung. In these the symptom-complex is much like that of the mediastinal tumors.

The disease is much more common in men than in women, and it makes its appearance nearly always after the fortieth year. It seems very probable that in the majority of cases the growth starts from the bronchial epithelium and not from the epithelium lining the air cells. Whether there is a primary carcinoma of the lung originating from the alveolar epithelium is not yet satisfactorily decided.

The growth of the tumor, in the opinion of Pässler, is in most cases along the lymphatic spaces, but not into the alveolar walls. He is also inclined to the view that small masses or groups of carcinoma cells, derived from a primary tumor projecting into a bronchus, may be aspirated into the bronchioles, and there give rise to secondary growths invading the alveoli. The histological character of the cells and the structure of the growth varies greatly in different cases,

all types of carcinoma apparently occurring. The cylindrical-cell form, however, seems to be the most common one. Metastasis takes place in a large majority of cases.

EXPERIMENTAL INFLAMMATION OF THE CORNEA.⁹

Goecke has studied the cells concerned in the inflammation of the corneas of frogs and pigeons, induced experimentally by injury to a small portion of it.

He finds that the fixed corneal cells assume a certain power of ameboid movement in the inflamed cornea and that the daughter cells which arise from these are contractile and capable of motion. They are typical wandering cells, in his opinion. These newly-formed ameboid cells move into the injured portion of the cornea, and there form new corneal tissue to replace that destroyed. Polynuclear leucocytes also appear from the neighboring vessels and carry off the dead material, etc.

NON-BACTERIAL TOXINS AND THE MECHANISM OF IMMUNITY BY MEANS OF ANTITOXIC SERUMS.¹⁰

From a series of experiments, Calmette and Delorme make the following statements:

(1) The serum of animals refractory to antitoxins which are not of bacterial origin, such as abrin and the venom of serpents, often rarely possesses antitoxic properties with respect to these toxins. The fowl, for example, and the turtle, resist large doses of abrin, but nevertheless their serum is totally inactive toward abrin. This is the same phenomenon which is observed with the bacterial toxins. Thus Vaillard has shown that the fowl, refractory to tetanus, gives a serum inactive toward the tetanus toxin.

When the serum of refractory animals is antitoxic, its antitoxic power is always only slight. There is, therefore, no relation between the naturally refractory condition of certain animals and the antitoxic power of the humors.

(2) The cold-blooded animals which are refractory are capable of producing antitoxin when they are injected with repeated doses of toxin, while, under the same circumstances, warm-blooded animals which are refractory do not produce antitoxin.

(3) Animals, such as the frog, are able to acquire an immunity to fatal doses of toxin without developing any antitoxic properties in their serum.

(4) The antitoxic serums for abrin and the venom of serpents can be utilized practically to give passive immunity to man and animals, and for the diagnosis of toxins in the practice of toxicology.

The anti-abrin serum possesses a very active preventive power when it is applied locally to mucous membranes and this property may permit its use in ophthalmology.

(5) The active substance of the antitoxic serum is not modified by chemical reagents which destroy or profoundly alter the toxins, nor does this substance alter the toxin when mixed with it *in vitro*. This active principle seems to exist normally in great abundance in the protoplasm of the leucocytes of vaccinated animals, and from these it diffuses into the blood serum and other organic fluids. It does not pass through dialyzing membranes. It has the property of acting energetically on the leucocytes of

⁸ Virchow: Arch. f. Path. Anat., Bd. cxlv, 1896.

⁹ Ziegler's Beiträge zur path. Anat. u. Allgem. Path., Bd. xx, 1896.

¹⁰ Annales de l'Inst. Pasteur, Tome x, 1896.

non-immunized animals in the same manner as the preventive anti-bacterial serums.

(6) Various substances having no specific action upon the toxins, such as bouillon, normal beef-serum, and certain serums of animals vaccinated against various infections or intoxications, can, when injected into non-immunized animals, manifest preventive properties toward various infections and intoxications.

Summarizing, the authors think that the immunity of naturally refractory animals, like the acquired immunity, ought not to be attributed to the presence in the serum of a chemical substance having the power to destroy or modify the toxins. In regard to the question whether there really exists a preventive substance in the serum of vaccinated animals, and whether this preventive power of the cells and of the humors is not rather a physical phenomenon like motility, inhibition, chemiotaxis, etc., the authors admit: (1) That the antitoxic power is independent of immunity, since the latter may exist when the antitoxic power is not manifest. (2) That the two kinds of immunity, natural and acquired, are the result of a special power of the cells, which, according to the conditions of their surroundings and according to the composition of their constituent elements (protoplasm and nuclear substance), undergo passively the influence of the toxins, in much the same manner as a piece of soft iron undergoes the influence of the magnet.

When, however, these conditions change under the influence of diverse external conditions, the functional state of the cells will also change, just as the piece of soft iron, transformed into steel by external influences, becomes capable of permanent magnetization and of transmitting this property to other pieces of steel. So, according to the authors, may be explained the susceptibility and the transitory or permanent resistance shown by the animal organism toward infection and intoxication.

HEPATIC CIRRHOSIS.¹¹

Van Henkelom has made a careful review of the many experimental investigations and histological facts which bear upon the question as to whether this condition of the liver is dependent upon a primary degeneration of the liver cells or not.

His conclusions are that cell degeneration and necrosis in the liver, of themselves, do not call forth any new formation of connective tissue which may be looked upon as a cirrhotic process and that in the light of the experimental work it would seem that cirrhosis is independent of parenchymatous degeneration.

Reports of Societies.

CLINICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

E. W. TAYLOR, M.D., SECRETARY.

REGULAR meeting, Wednesday, December 16, 1896, DR. W. F. WHITNEY in the chair.

DR. H. F. VICKERY read a paper on

HEMOPHILIA.¹

DR. H. P. BOWDITCH: I was rather surprised to hear, if I understood the reader rightly, that the blood

¹ See page 226 of the Journal.

¹¹ Ziegler's Beiträge zur path. Anat. u. allgem. Path., 1896.

in these cases has the normal power of coagulation. I have always supposed it was deficiency in the coagulating power of blood which was the essential cause of the bleeding, and the proposed methods of treatment certainly indicate that this is the case.

The question of the coagulation of the blood has been of great interest to physiologists for many years. The striking character of the phenomenon by which a liquid circulating through the blood-vessels becomes a gelatinous solid as soon as it leaves them, early attracted attention and demanded then an explanation. The simple experiment of stirring the blood to defibrinate it showed that the cause of the coagulation was a stringy material receiving the name fibrin. The nature and origin of fibrin became then an important study. The chemical analysis showed it was of proteid composition, but it is interesting to note that the earlier chemists in endeavoring to get pure fibrin were never able to get rid of the mineral substances, the ashes. Specimens of fibrin always contain a certain amount of mineral material, notably the tribasic phosphate of lime. They regarded it as an impurity, something attached to the fibrin, but not a part of it. We know now that in all probability this is an essential constituent of the fibrin molecule. It is interesting that our predecessors of thirty years ago should have worked so hard to get rid of it as an impurity.

It is difficult to understand how one and the same substance can be at one time, soluble and liquid in the blood and subsequently insoluble in plasma and serum. The conclusions therefore would seem to be that the blood does not contain fibrin already formed, but some substance which becomes fibrin after the blood is drawn. This is a view which Virchow emphasized very strongly. A further advance in the same direction led to Schmidt's theory which for a long time held its ground as the only practicable theory, namely, that there are two substances in the blood, fibrinogen and fibrinoplastic substance, neither coagulable in themselves but by their union forming fibrin. Soon it was found there were cases where both these substances might be present and yet coagulation did not occur. This led to Schmidt's theory being enlarged by the introduction of fibrin ferment which was necessary to make the fibrinoplastic substance unite with the fibrinogen. Subsequently Hammarsten's theory was advanced, in accordance with which the fibrinogenous substance alone is necessary for the formation of fibrin; this acted upon by the fibrin ferment becomes fibrin. The nature of the ferment was not made clear by Hammarsten, and it is to the elucidation of this subject that the newer researches have been directed. Hammarsten's work and that of Arthús led Schmidt to develop a new theory of coagulation published a few years ago in a work on the theory of the blood which represents the results of Schmidt's labors of a lifetime. According to the newer theory the blood contains a series of different proteid bodies, one derived from another and all having their origin in the tissues generally of the body. According to Schmidt's view the fibrin may have its origin in any of the tissues except perhaps the red-blood globules. According to his present views the substances take their origin in this order: first, a substance called cytin, insoluble in water; second, cytoglobin, soluble in water. This circulates in the blood and subsequently gives rise to a third substance, known as preglobulin, which is insoluble in water, but, like other globulins, soluble in salt

solution. Derived from that we have the paraglobulin, one of Schmidt's original fibrin generators. We come now to the substances with which we are familiar from the earlier history of the subject. Paraglobulin then gives rise to the second fibrin generator or the fibrinogen, and that, being recognized as a globulin, is now to be called metaglobulin. That is the name Schmidt now proposes for what he formerly called fibrinogen. Paraglobulin circulates in the healthy blood and the fibrinogen is formed from it under the influence of a ferment. This is as far as the process goes in the healthy circulating blood. Under the influence of the fibrin ferment the paraglobulin is changed into fibrinogen, and that again gives rise to the formation of what Schmidt calls soluble fibrin, that is, fibrin which is not in the form in which it is precipitated out from the blood, but which is contained in the blood in liquid form, until it reaches a certain density, when it reacts with the salts contained in the blood and is precipitated as fibrin. You see at once that Schmidt has maintained the necessity for paraglobulin, while in Hammarsten's theory paraglobulin has absolutely nothing to do with the formation of the clot. In Schmidt's new theory it is not an accessory to the formation of the clot as in the former theory but is essential as a precursor to fibrin.

The most recent work has been directed mainly to the determination of the relation of the salts to the fibrin and here Arthus has done more than any one else. He has recently published a theory in accordance with which the fibrin ferment changes the fibrinogen by splitting it up and a part unites with the lime salts of the blood and forms fibrin. If that theory is correct this part of the fibrinogen which splits off from the fibrinogen molecule to make the fibrin, must weigh less than the whole of the fibrinogen, and Arthus has reached experimental results which he considers conclusive in favor of this view. On this theory, moreover, we ought to find that the removal of the lime from the blood must hinder coagulation and that has been found to be the case by Arthus's experiments in which the blood was treated with alkaline oxalates. Schmidt says that in this case, the blood fails to coagulate not because the lime has been removed but because oxalates have been added. The question on this point has been fought out with a good deal of vigor and it cannot be said that absolutely satisfactory conclusions have been reached. Furthermore, if this view is correct, that a portion of the fibrinogen unites with lime salts to form fibrin it would seem that the amount of fibrin must increase with the lime salts of the blood, and this appears to be true. There seems to be no doubt that up to a certain point increase of lime in the blood does increase the amount of fibrin. It is not in direct proportion to it, but does increase with it. It is evident therefore that lime is an essential part of the fibrin molecule in some way or other.

The nature of the fibrin ferment remains to be considered. What is this material which causes the change of one of these proteids into another? It has been generally agreed that the leucocytes and the blood-plates furnish by their breaking down a substance which acts as a fibrin ferment, and two recent observers have succeeded in isolating a nucleoproteid body which seems to have this power, and they have recently advanced theories on the subject which have a good deal in common, but differ in some of the details. The theory of one of them (Pekelharing) is

that a nucleoproteid body, which is set free by the breaking down of the blood-plates and leucocytes, unites with the calcium salts of the blood to form what may be called a fibrin ferment. It is an organic substance which reacts with the fibrinogen, breaks up the fibrinogenous molecule and forms fibrin. The second theory, that of Lilienfeld, is that the nucleoproteid is itself the fibrin ferment and does not need to unite with the calcium salts; that it breaks up the fibrinogen by its catalytic action and a part of the fibrinogen which he calls thrombosis unites with the lime salts to form fibrin. Three things are necessary to make fibrin—fibrinogen, nucleoproteids and calcium salts, and exactly how they react to form it is a question for future investigation. It is probable we shall never be able to come to a satisfactory conclusion until we know a great deal more about the formulæ of proteid bodies generally. Until a good deal of advance is made in organic chemistry we must leave the ultimate cause of coagulation very much in the dark.

DR. A. H. NICHOLS thought that with the hemorrhagic diathesis the danger of post-partum flooding was probably greater than was generally represented. If experience on this point is limited, it is to be ascribed to the fact that very few hemophilic women grow up and marry, as can be illustrated by a simple calculation. If we take, for example, 1,100 children born with this malady, inasmuch as males are affected more frequently than females, in the proportion of 10 to 1, but 100 of this 1,100 will be daughters. Now of these 100 females it is certain that the great bulk will be cut off in infancy or early childhood by hemorrhages produced either spontaneously or by insignificant accidents. Indeed, the rate of mortality is so great in some families as to involve their absolute extinction. Assuming, however, as per estimate of Swett, of New York, that one individual in 18 will reach the age of puberty, then of these 100 females less than six will attain the procreative period.

DR. H. P. BOWDITCH asked if diminution in the number of leucocytes may not perhaps favor the tendency to bleeding. When slight capillary hemorrhages are observed under the microscope a collection of leucocytes is seen to take place around the bleeding point and these, by their viscous character, seem to plug up the opening. Inasmuch as the bleeding in hemophilia is noticeable more in capillary regions than where arteries are wounded, it seems to me that diminution in the number of leucocytes may be one cause that contributes to the production of the phenomenon.

DR. VICKERY: It has seemed to me that in spite of what is not found after death, the fact that these patients suffer so much from ecchymoses under the slightest traumatic influences, such for instance as this patient of ours whose friends in lifting her from the cradle would make black and blue spots, shows a fragility in the vessels. And about the coagulability of the blood, of course it must be unquestionably in many cases difficult to coagulate it; yet sometimes there will be a large clot outside of the bleeding-place, the bleeding still going on. Until I read up the subject I had an idea that fewer women suffered from hemophilia than really do. There are a good many cases. As to the chance of women who are bleeders who come to have babies, the statement is distinctly made by some authorities that while the first menstruation is often profuse, yet most of these hemophilic women go through childbirth without post-partum hemorrhage.

THE MUSICAL FACULTIES IN HEALTH AND DISEASE.

THE psychological and cerebral relations of the musical faculties have of late years been the subject of considerable study, the results of which have recently been summed up in an interesting article by Ferrari.¹ Although the musical faculties are akin to the general faculties of speech, and are by some supposed to be evolved from them, harmony of sounds appears very low in the animal scale, probably much before speech develops, and certain races speak by monosyllables which have different meanings according to their accent. Certain children, too, learn to sing in harmony or to appreciate music before speech develops. The musical expression apparently needs a much simpler psychological apparatus than that of speech, which explains the occasional musical development of idiots. On the other hand there are persons of good intellectual and esthetic development who can not distinguish one note of an octave from another. As is well known, musical faculties are more frequently inherited than are other faculties.

The physiological action of music has been noted by various writers. Lombard has noted its influence on the knee-jerk, and Dogiel on the circulation; the latter finding in man and animals that the auditory excitement from music was accompanied by oscillations in the circulation dependent ultimately upon the pitch, the intensity and the timbre of the sound. Others have found that music affects muscular activity and the respiratory changes. Some studies on an apathetic and thus unsatisfactory subject, with a trephine hole in his head, made by Patrizi, indicate that music causes an increase in the amount of blood in the brain, and Ferrari himself and Vigna have noted a variation of the pulse synchronous with the rhythm of the music.

Upon the psychological side a few observations

Rivista Sperimentale di Freniatria, xxii, 324, 1896.

seem to indicate that low tones require a longer reaction time for perception than high tones, and that the time varies with the intensity of the sound. Gilbert in school boys, found the musical sensibility to increase with age up to nineteen years, but most rapidly between six and nine. Stricker held that musical representations were dependent upon sensations of movement in the larynx, but Wallaschek proved that the musical image was not simple, but that it might be associated with other processes in the organism which of themselves have nothing directly to do with musical representations. This associative factor is of greater importance in music than in speech, because speech, by defining, limits our psychical activity, while music, by exciting, widens it. Thus musical ideas may be of visual, auditory, motor, and mixed types, and a number of instances are recorded where music has aroused definite and distinct visual impressions, sometimes associated with colored hearing, or, much more frequently, with motor impressions, as when music is associated with the movements of the dance. Those in whom music arouses auditory impressions alone, have merely tonal impressions, and thus, from the artistic point of view, belong to a lower type, to whom music is merely a combination of tones, a formal play of the intellect, but in whom it arouses no wider associations.

The pathological disturbances of the musical faculty, some of which have been classed under the heading of amusia, are usually related to the analogous disturbances of language. These have been classified most elaborately by Wallaschek to harmonize with the varieties of speech disturbance, but as only about twenty cases are on record, the classification is more theoretical than practical. The most common forms, according to Brazier, are vocal motor amusia, where motor images relative to singing are lost, and instrumental motor amusia, where images relative to playing are lost. Brazier cites an interesting and unique case of tone deafness, where this was the only symptom, there being absolutely no word deafness or psychical deafness besides. Visual amusia, note blindness or musical alexia, has also been described. Although as a rule amusia is a corollary of aphasia, it may sometimes, as in such cases, be wholly independent of it.

In mental diseases the musical faculties may persist when other faculties fail. Wildermuth thought that about one-third of idiots had a good musical capacity, but Ferrari, who has himself experimented on this point with Bernardini, puts the percentage much lower. Legge, too, has found that in dementes the musical faculties disappear along with other esthetic faculties, before the mental powers have departed. In mania there may be musical incoherence, in stupor and melancholia the patients lose all interest in music, and in general paralysis musical ideas may become grandiose. Irresistible impulses to sing or play are sometimes noted, and musical hallucinations may also occur.

From the days of Homer and Saul music has been commended in the treatment of disease, but the reported benefits are to be received with some scepticism. Ferrari suggests that we can probably find in music only a massage of the hearing, or a sort of vibratory cure of the cephalic centres. In times past the Sorbonne pronounced music efficacious in disease, and Lichtenthal and Porta prescribed definite melodies and used violins made of special woods, poplar or hellebore, against fever and ascites. Even at the present day Maillet has argued that the use of the piano or violin promoted the growth of the hair, but that the use of brass instruments had the contrary effect. Various men have obtained some analgesic effect from music, but its benefits in disease are probably due solely to its power to amuse and divert.

THE WINTER MIGRATION.

DURING the months of January, February and March many of the well-to-do inhabitants of our Eastern States, and especially of the cities along the Atlantic sea-board, leave their homes for weeks or months and seek at the South—in North and South Carolina, in Georgia and in Florida—that climatic equability and moderation which, out-of-doors, is denied them at home. This migration southward and return northward has at length become almost as regularly periodical a phenomenon with human beings as with birds; and as there are no sportsmen to pick off the men and women who indulge this migratory tendency, their numbers increase. The fact that the numbers do increase tends to show that experience proves there is an excess of pleasure and profit over inconvenience and risk from these changes. At least that inference may be drawn, except in so far as the influence of fashion and the force of habit vitiate it.

That there are inconveniences and risks cannot be denied. People with a sensitive respiratory apparatus or insufficient general vigor can be more in the open air at the South, it is true; but, on the other hand, the anticipated climatic equability and moderation are not always found, as witness the frozen orange-groves of Florida. An extreme confidence is not infrequently treacherously betrayed. A recently migrated patient writes from Florida: "The air is delightful, but I have a tonsillitis." Then there are the risks of tuberculous sleeping-cars and hotel bedrooms. Perhaps these are no greater, though more continuous, than those of street-cars and places of public entertainment at home.

Then there is the inevitable struggle for the best places on crowded trains and the best or any rooms at crowded hotels. And the more crowded the trains, the more pre-empted the hotels, the greater the proof to some minds of desirability, and the more eager the wish to be part of the pilgrimage. Then there is the question of coming back. The return is apt to be too early or too precipitous.

Then, in addition to these regular and certain drawbacks or inconveniences, there are others which may be classified as casual or fortuitous. Of these, two instances have chanced to come to our notice during the last twenty-four hours. A train fails to make connections, and a delicate lady has to stand in a crowded car from Baltimore to Washington; at Washington she is separated from her trunk, which is forwarded by a well-known express company; the express company lets the trunk fall into water, ruins an expensive wardrobe, and offers fifty dollars damages. Instance number two: a gentleman telegraphs his wife at a well-known health resort in Florida not to come home on account of bad news. At the end of twenty hours he receives a reply from the hotel that his wife has gone North. He telegraphs for particulars, and eventually is informed that the first telegram was a mistake, that his wife had only gone out to walk.

We have no desire to unduly decry the winter begira, but it is fair to warn those who join these birds of passage, and also those who profess to care for them in transit and after arrival, that the change is neither an unmixed good, nor an unmixed pleasure, nor an unalloyed comfort. It is worth while to suggest that there is an alternative, of which, after the manner of the serial *à la mode*, we propose to say a word in our next issue.

MEDICAL NOTES.

BOSTON AND NEW ENGLAND.

RESIGNATION OF DR. PRATT. — Dr. John W. Pratt has resigned his position of Superintendent of the Massachusetts General Hospital, which position he had filled most satisfactorily for sixteen years. Dr. Herbert B. Howard, who is at present Superintendent of the State Almshouse at Tewksbury, Mass., will succeed Dr. Pratt on June 1st.

BEQUESTS TO MEDICAL CHARITIES. — By the will of Mrs. C. V. R. Thayer, of Lancaster, Mass., widow of the late Nathaniel Thayer, the following public bequests were made to medical charities: to the Boston Home for Incurables, St. Luke's Home for Convalescents, Children's Hospital (to be used for the Convalescent Home at Wellesley), House of the Good Samaritan, Boston, \$5,000 each; to the New England Hospital for Women and Children, the Massachusetts Ear and Eye Infirmary, and to the Boston Lying-in Hospital, Boston, \$10,000 each; to the Massachusetts General Hospital, for free beds, \$25,000.

LECTURES ON CLIMATOLOGY BEFORE THE HARVARD MEDICAL ALUMNI ASSOCIATION. — On the invitation of the Harvard Medical Alumni Association, Mr. Robert DeC. Ward, Instructor in Climatology in Harvard University, will deliver four lectures on General Climatology and its bearing upon Medical Climatology, at the Harvard Medical School, Boylston Street.

The lectures will be given in Lecture Room C. on the four successive Tuesdays, March 23d, March 30th, April 6th and April 13th, at 8.30 p. m. In addition to the members of the Medical Alumni Association, the members of the Faculty and the students of the Harvard Medical School are cordially invited to attend these lectures.

NEW YORK.

DEATH OF DR. HUNTINGTON.—Dr. Henry K. Huntington died suddenly, of cardiac disease, at his residence at City Island on February 28th, in the fifty-second year of his age. He was born in Hartford, Conn., March 27, 1845. He was graduated from Trinity College, Hartford, in 1866 and afterwards from the College of Physicians and Surgeons, New York. After serving on the house staff of Charity Hospital, Blackwell's Island, and later as resident physician and surgeon at the Convalescent Hospital on Hart's Island, he removed to New Rochelle, Westchester County, where he resided for twenty years and built up a very large practice. For a number of years Dr. Huntington was Health Officer, and also President of the Board of Education, at New Rochelle.

DEATH OF DR. ILGEN.—Dr. Ernest Ilgen, a native of Bavaria, died at his residence in Brooklyn on March 5th, at an advanced age. He was formerly an active member of the Burschenschaft, in Munich, but, incurring the enmity of the authorities, he was obliged to leave the country in 1851. After his arrival in America he began the practice of medicine in Brooklyn, where he achieved a high reputation as a specialist in diseases of children.

Miscellany.

A NEW BULLETIN OF THE HARVARD MEDICAL ALUMNI ASSOCIATION.

THE Harvard Medical Alumni Association has just issued Bulletin No. 10. This is a well-arranged and very useful catalogue, prepared by the Treasurer, containing the names and residences of all the members. This rapidly growing and prosperous organization, founded in 1890, has now on its rolls more than two-thirds of all the living graduates of the Medical School. There are 1,238 members, scattered throughout thirty-six States and Territories, Canada, Mexico and several foreign countries.

The annual bulletins, containing the reports of the meetings and the speeches of the distinguished medical guests at the dinner, are always of interest, and show how well the society is fulfilling its purpose of advancing the cause of medical education and increasing the usefulness and influence of the Harvard Medical School.

The Association, which all graduates of the school, including the members of each year's graduating class, may join, is to be congratulated on the good work it is doing.

Correspondence.

SURGERY UNDER KOCHER AT BERNE.

PARIS, February 24, 1897.

MR. EDITOR:—Prof. Theodor Kocher, of Berne, is a surgeon whose reputation is of wide extent both this side of the ocean and in the United States. Although we know him through his writings, with his personality and his methods as teacher and operator we are not familiar. I trust, therefore, that your readers will find the following details interesting.

Kocher is now about fifty-five years of age. Slight, erect, active, five feet and six inches in height, with iron-gray hair brushed smoothly back from a high forehead, a brownish-gray beard and moustache closely clipped, eyes of a cold gray until his bright smile makes them warm and winning, a straight, handsome nose and extremely fine profile, Kocher, who is always neatly and well dressed, is a very attractive and noticeable man. He was made professor at the unusually early age of thirty-one years, and is the chief object of interest in the medical department of the University of Berne.

Indefatigable, and capable of performing a prodigious amount of work, winter and summer he rises at 5.30 A. M., and, during waking hours never knows one idle moment. By 7.30 A. M. he is usually to be found among his patients at the Insel Hospital. On five days in the week he begins his clinic at 8 A. M., and thereafter operates until 1 P. M. Once weekly he gives a didactic lecture upon the principles of surgery. Several times during the week, in the afternoon, he makes an additional round among his hospital patients. On four or five days in the week he operates in one or the other of two private hospitals. With the exception of a three weeks' vacation in summer he takes no rest, has no recreation, but works unceasingly from early morning until his bed hour. He does not smoke nor does he touch wine, which, in a European, is very exceptional. He is also phenomenally frugal at table.

His private practice is immense and his patients comprise every rank, including royalty. He is noted for his kindness to those of his patients who are poor. He is called in consultation not only throughout Switzerland but to surrounding countries as well. A voluminous writer, Kocher is author of nearly 4,000 pages of printed matter, including his lengthy and superb folio work upon "Gun-shot Wounds and the Force of Projectiles." He devoted years of labor to this work. His "Operations Lehre" has passed through two editions, the first having been published in 1892. The second (1894), was out of print long ago; and a third, enlarged and perfected, is now being published.

In spite of his unceasing and exhausting activity, I have never seen Kocher show the slightest sign of fatigue, nor have I ever heard, touching any other medical man, such glowing tributes as have come from his private patients, many of whom I have met and all of whom expressed toward him the same warm feeling. I could also see that his hospital patients loved and revered him. His manner toward them is always one of deep interest. At the bedside he is simple, unconscious, very winning and completely absorbed in the case before him. I have frequently met Kocher at the bedside of a private patient, late in the evening, after a day of work the amount of which would have tired two ordinary men, his dinner hour having been long forgotten, and he was always the same bright, cheerful, sunny man.

Even his assistants look upon him with wonder, for, excepting from them the same alertness and activity which are peculiar to himself, they are taxed almost beyond endurance and, as one of them confessed to me, so arduous is the discipline which they undergo, that some of them, but for the reputation which they gain by the honor of having been upon Kocher's staff, would resign their positions, and yet, their chief works far harder than any one of them.

He has been twice requested to accept a chair of surgery

in Berlin with tempting emoluments. But he prefers, and rightly, his friends think, to remain in Berne where he is king.

The people of Berne are prouder of Kocher than of their bears, and one who has brought a patient to Kocher, especially a foreigner, has only to mention the fact in order to receive from the railway officials the most pressing and courteous attention.

Given a man of Kocher's activity, precision, thoroughness and erudition, one would naturally suppose that a clinic conducted by him must be something unusual; and Kocher's clinics are unusual and he is a rare teacher. He is never eloquent, but always incisive, remarkably lucid in statement, not multiplying phrases but thoroughly exhausting every bearing of the case under consideration; he is gifted, too, with a power of sustained, uninterrupted speech, never hesitating for a word. His diction is calm but alive with vigor and trenchant phrase. Throughout sparkles a crisp, quiet humor, made evident by the merest touch in word, more by a quick, bright smile which is contagious.

Kocher's diagnostic ability is exceptionally many-sided. He is equally at home whether examining a hidden tumor, a diseased lung, an abnormal heart, an affection of the skin, a case of renal disease, a result of cerebral or spinal malady, a specimen of urine, a pathological or bacteriological preparation under the microscope. In pure surgery he is a master. His delineation of a case evinces great familiarity with writers of all lands, with the opinions of all authorities.

He opens his clinic by calling two students to pronounce a diagnosis of the case in hand which often they have previously examined. His manner with them is gentle and kindly but thorough to the last degree, for no point is left untouched and one of the students, perhaps, is called upon to go to the blackboard, sketch the limb or what not and, with colored chalks, show the relations of muscles, bones, blood-vessels and nerves, the site of glands, bursae, etc. Kocher will not release a student until the latter is clear as to the nature of the case, even though his professor find it necessary to guide the hand and direct the touch of the student with his own hand.

Kocher's clinics are models of perfect instruction. Every accessory in form of skeleton, bones, wet and dry preparations, models, colored anatomical plates, blackboard sketches (in which Kocher is very clever) and the microscope, are profusely used. Every wound is at once tested by the bacteriologist who, whenever it be possible, quickly brings a preparation of the bacillus or coccus for the inspection of the students and gelatine or bouillon is inoculated for future study. At every clinic whatever has been removed from the bodies of patients on the previous day is fully described and then passed around the class. If their knowledge of anatomy be imperfect the students before the class are liable to become embarrassed by Kocher's questions which are very searching. But such are his methods and so thorough is his painstaking care that a student who failed to carry away a vivid conception of the patient's condition must be dull indeed.

So many accident cases, in the condition in which they came to the hospital, are brought before the class, that students enjoy abundant opportunity to reduce fractures and dislocations and advise treatment under Kocher's help and suggestion. As will be seen this is a strictly practical and instructive clinic.

Kocher's brilliant power to make a diagnosis by exclusion is very impressive.

At his clinic are always visitors who comprise cultured surgeons from various countries. The judgment of those who were present during my stay in Berne (eight weeks, during which I did not miss a clinic) was uniformly the same, namely, that nothing could be more perfect nor more classic than Kocher's delineation of a case and especially his differential diagnosis. One of these, a surgeon at the head of a hospital containing 250 beds, himself a German and who was educated in Berlin and Heidelberg, and another surgeon, chief of a large Austrian hospital, told me they had made themselves familiar with the operative methods of the leading surgeons in Germany, France and

Austria, and that they considered Kocher *facile princeps* as operator and teacher. The first of these gentlemen added that if he had a son who wished to make surgery a specialty, he would send him to Kocher and not to Berlin.

I would advise young American surgeons, who come abroad to study, not to fail to give several months to Kocher's clinic. Material is abundant, operations are profuse in number and variety and the treatment of medical visitors to the medical school of Berne is courteous in the extreme. The visitor would find it worth his while to make a stay in Berne simply to become familiar with Kocher's operations upon goitre. In this field his experience is very large. Up to January first, of the current year, Kocher had operated upon 1,236 cases of goitre, and in these cases, since he perfected his operation, his death-rate has been less than one per cent. This information was given me by Kocher in person.

In passing I will allude to the distinguished service of Kocher, as chief of a commission of 25 physicians, in examining 76,666 school-children of the Canton of Berne for goitre. He not only passed these children in review, or edited and decided upon the statistics passed in by the other physicians of the Commission, but also made, throughout the towns and villages of the canton in valley and upon mountain, a thorough search for the cause of goitre. The results of this large labor are to be found in a pamphlet written by Kocher, illustrated by a beautiful map and published by the authorities of Berne. To these results I shall refer in another letter.

Visitors to Kocher's clinic will find a knowledge of the German language a *sine qua non*. Even with this aid, however, they will sometimes be at fault, for Kocher is obliged to question many patients in Swiss-German and many others in French. He is equally fluent in English.

His class numbers about one hundred students, sixteen of them, for the most part Russian, being women. These young women possess singularly dull and unattractive faces, and, while they pay strict attention and take copious notes, their reputation for ability does not flatter them. They are allowed to witness Kocher's operations in the private room to which he retires after the regular clinic, that is, they take their turn among the students, six of whose names are written upon the blackboard at each clinic, in token that these six are requested to be present at the operations.

The operating-chamber is of the regulation pattern of iron and glass, having a concrete floor containing drainage-holes for the escape of the sterilized fluids which are used during the course of operations. Opening into this room are two steam-chambers, which have a temperature of 150° Centigrade (300° F.) and a pressure of three atmospheres. Kocher considers damp heat the best means of asepsis. From these chambers are taken all clothes, sheets, aprons, gauze compresses and metal boxes of *Tupfen* (small folds of gauze which are used instead of sponges). The operating-table is a frame of iron having a hollow bed of best burnished copper kept filled with hot water, and moulded to the body in such fashion that the trunk and legs of the patient are higher than the head. There are several similar tables, a patient and one table being wheeled into, as another is wheeled out of the room. A broad, padded strap confines the body of the patient to the table and one of the patient's wrists is held by a leather loop the free end of which is passed over and under the table.

There are four assistants: one is at the wound; one gives ether; another watches the pulse; the fourth, in this case a "sister," supplies Kocher with instruments, *Tupfen*, cloths, fluids, etc., and she is a wonder of quickness, dexterity and forethought. All wear heavy, loose rubber overshoes, rubber gowns which reach the floor and are covered by linen frocks which fall to the knees, and are taken hot and damp from the steam-chambers. On the heads of all are sterilized-gauze caps. This costume is a necessity because, during operations, so much hot water is used that the surgeon and assistants otherwise would become drenched to the skin. Before operations the rubber

gowns are washed always with a corrosive-sublimate solution and attempts to find germs upon them have proved negative.

Kocher rarely employs chloroform. As an anesthetic he uses ether almost without exception. In cases in which it is necessary to avoid all possible irritation of the bronchial mucous membrane, as well as emesis, Kocher operates without an anesthetic. In his clinic narcosis is begun by pouring a half ounce of ethyl bromide upon the ether mask. Within thirty to sixty seconds the patient is unconscious, and the condition is continued by the administration of ether. This practice is sensible because the choking sensation caused by ether at the beginning of the anesthesia, and which costs time, is thus avoided. Ethyl bromide is convenient for operations of brief duration.

Kocher's instruments and bandages are cooked thirty minutes daily in boiling water or in a solution containing 7.5 per cent. of table salt and two per cent. of soda bicarbonate. Bandages are always of gauze deprived of fat. Drainage-tubes are glass with slightly knobbed surface; ligatures are invariably silk, Kocher having discarded catgut six years ago. His sterile silk ligatures are kept in corrosive-sublimate solution.

Before he operates and after cleansing his finger-nails with instruments, Kocher washes his hands and nails several minutes with a brush and soft soap under running hot water, then two minutes with brush and sublimate solution. He advises surgeons who find the sublimate irritating to use a one per cent. and warm solution of lysol, and further advises washing with disinfected brush in sterilized soda or salt water, of which solution I have already given the preparations. Kocher values this solution highly.

In operating Kocher dresses wounds by a profuse use of sterilized water from the steam-chambers, and finally with lysol or sublimate gauze; but unless a wound be purulent, like an abscess, or empyema, antiseptic solutions are rarely poured upon it. If a wound be washed out with a two-per-cent. sublimate solution a thorough drenching with a 7.5 per-cent. solution of hot, salt water follows. The first covering of the wound is a hot, damp, sterilized gauze, followed by a layer of sublimate gauze. Closed wounds are covered with sterilized gauze made adherent by collodion. The usual gauze dressing is then added. In closing a wound Kocher never uses an interrupted suture, but sews the lips together from end to end by an over-and-over stitch. Where there are heavy layers of muscle, he first unites the divided muscles in this manner and secondly the skin. He seldom inserts a drainage-tube into the wound itself, but, making an incision in the inferior lip of the wound he pushes the tube through this opening. Basins of hot water, sterilized by carbolic acid, sublimate and lysol, stand in a row upon tripods. During operations Kocher washes his hands very frequently in one of these solutions; and, in short, as to all possible means of asepsis he is the strictest of martinet, and requires the same care from his assistants. An illustration of the perfection of his asepsis was shown by a case of exarticulation of the femur, healing occurring in two days. His goitre cases are discharged usually at the end of ten days.

Instruments lie in solutions in nickel-plated trays upon a tripod arranged like a bed-table, so that when pushed up to the operating-table the trays are immediately over the patient.

Kocher is extremely particular as to the condition of the stomach during the twenty-four hours preceding an operation. For example, an operation is to be made at noon: On the previous evening the patient is given a cup of tea and a rusk; at 5 A. M. the next day he has a cup of tea containing two or three teaspoonfuls of brandy. With these exceptions the patient receives no food until the evening following the operation. With slight modifications this is the course regularly followed. Kocher, however, in some cases likes to give a dose of brandy immediately before the operation. This care is taken even in a simple case when the narcosis is to be of brief duration.

The preparation of the seat of operation consists of the usual shaving and scrubbing with water and soap followed

by sublimate solution. An antiseptic bandage then covers down a heavy gauze pad. This is done an hour or two before the operation, directly preceding which the bandage is removed, and the same twofold scrubbing is thoroughly repeated, being completed only at the moment when the knife enters the tissues. When the patient is removed from the table, the wound being already perfectly dressed, he is carried to his own bed, which has been wheeled upon a bed truck to the operating-room, and there, by means of flat, oval, metal boxes filled with hot water and which have already warmed the bed, and by warmed blankets, he is made comfortable. This avoids the usual second change and the possible disturbances of the customary methods of transfer.

The amount of subordinate work performed by Kocher and the attention which he gives to minute details, which in my experience surgeons usually pass by or relegate to assistants, is astonishing. He neglects nothing, is unflaggingly particular, and unless pushed for time always dresses a wound with his own hands. He has the reputation of doing with success, operations which other surgeons decline because of their apparent hopelessness or because of the danger to the patient which the operation would involve. This reputation is not only popular but proceeded from the profession. At the operating-table his quiet courage and calm decisiveness, his coolness and even cheerfulness under every surgical exigency, seem almost inconsistent with Kocher's slight figure and delicate appearance, but he is as tough as a fisherman of the Grand Banks. He has great delicacy and surety of touch, swiftness of movement and flexibility in manipulation. This is especially evident in operations upon goitre, which, because of the large number of arterial forceps required, the very numerous blood-vessels and the obstacle imposed by the tumor itself, are a very bothering and trying procedure. It would seem far more trying to patients who undergo the operation without ether. Whenever he can gain the consent of the patient, which he succeeds in doing surprisingly often, Kocher prefers to do this operation without the anesthetic. His reasons for this are the dyspnea, from an almost invariably existing compression of the trachea, and the liability of coughing and emesis. In one forenoon I saw Kocher operate for goitre upon three patients, two girls and a lad whose ages averaged seventeen years, without ether. After making his usual semilunar incision, which merely penetrates the cuticle, an injection of a one-per-cent. solution of cocaine was given through a long flexible needle throughout the course of the incision. This was the only anesthetic which was used; and this, of course, influenced the skin alone. During the operations which followed the patients made hardly a sound, and their courage and self-control were characteristic of the Spartan endurance which seems peculiar to the Swiss patient when under the knife. There must have been a large degree of suffering in these cases, for, given a heavy tumor attached to the trachea in a neighborhood rich in nerves, the tumor having an additional weight of forty to sixty arterial forceps and being tossed from side to side during the progress of dissection, averaging thirty minutes in each case, one can easily imagine that great discomfort must ensue. Kocher's arterial forceps weigh eighteen grammes each. Fifty of these would add about two pounds to the weight of the tumor. The integuments are re-united by the continued suture, and two weeks later, the cicatrix is merely a thin red line. In doing this operation Kocher is extremely careful to prevent bleeding, and the amount of blood which is lost is small.

Another feature of the surgical clinic of Berne is peculiar also to the medical clinic (conducted by Professor Sahli whose book on "Methods of Diagnosis" is the best I ever saw of the kind), and this feature is the thoroughness with which cases are examined and followed. I have seen patients brought before the students in a dying condition. This seems severe for the patient, but is of great value to the student. On the day following an operation Kocher almost invariably has the patient wheeled into the lecture-room in order that the students may observe his condition.

In all medical clinics which I had previously attended it was generally made possible to present several patients during the period of the clinic. In Berne a case of muscular insufficiency of the stomach occupied two entire clinics; a case of syphilis, with consequent paralysis, three clinics; a case of locomotor ataxia and a case of supposed fecal tumor, three clinics each; and in the latter case a transfusion of salt water was made before the class, the patient being in a moribund condition. A case of pneumonia during the height of the disease was wheeled in upon her bed and examined by a student. This is thoroughness to the last degree; and yet, such care is exercised, such gentleness is used, the patient is kept so warm, that objection to this course would seem needless. The patients were invariably calm and apparently willing to be thus used. Entire bodily exposure of both sexes is the rule and appears to be a matter of course.

The skin, the eye, the throat, urine, sputa, the response of muscles and nerves to the galvanic current, the general expression of the face, the position of the body in bed, the condition of all the organs are all noticed, tested and considered.

The *Praktikant* (the student called to the patient) is expected to examine the urine for every possible ingredient which has a bearing on the case. He is called upon to examine the blood by means of a spectroscope, to make a laryngoscopic examination of the throat, to diagnosticate the condition of heart and lungs and express his results on the blackboard by a system of signs invented by Sahli. Percussion and palpation he must apply exhaustively.

In the entire course of teaching in this school, simplicity, directness and utter absence of self-consciousness on the part of teacher, student and patient are strikingly apparent. The one aim is scientific thoroughness and exactitude.

Kocher has won large fame for his radical cure of hernia, for gastro-enterostomy in cancer of the stomach, for his operations on goitre, his discovery of coxa vara, his methods of reducing luxations and other procedures in which he has shown great ingenuity and originality. In varicocele, serotal hernia, and hydrocele he never opens the scrotum but makes his incision above and parallel to Poupart's ligament. Through this incision the parts involved are drawn and the effusion emptied. In fracture of the patella he passes strong silk ligatures through the fibrous envelope of the fragments. Such is the earnestness with which bacteriology is studied in this school that the authorities have just erected a handsome and spacious building, which will be devoted to this branch of medical science under Professor Tavel, whose reputation has reached a high degree.

With the other departments of the school I am less familiar, but sufficiently so to say that while surgery and clinical medicine are both taught excellently well, surgery brilliantly and exceptionally so, the remaining chairs of instruction are well sustained. Any specialty may be studied here. Pathology is carefully taught and the post-mortems are made as finely and with as much exactitude as in Berlin or Vienna.

Very truly yours,

H. O.

DEFICIENT RESPIRATORY CAPACITY THE HEREDITY CAUSE OF PULMONARY TUBERCULOSIS.

OTTAWA, ONT., March 1, 1897.

MR. EDITOR:—As there is evidence tending to prove the theory that all persons predisposed by heredity to consumption have a respiratory capacity or action insufficient for good vigorous health—probably a proportionately small chest with insufficiency of lung membrane; that the predisposition is mainly or primarily due to this cause; in other words, that the insufficient respiratory function is the special primary feature of the predisposition (a condition which may be, practically, acquired by habit, occupation, etc.), I desire the co-operation of the profession in an endeavor to help to establish, by means of collective investigations, the correctness (or otherwise) of this theory.

In this behalf I hereby ask all physicians who have patients predisposed to, or in the early stage of, consumption, to send to me (a post-card will suffice) the information below indicated. As soon as I can study and collate the replies, I shall make the results known to the profession.

Give (1) name (or initials); (2) sex; (3) age; (4) occupation; (5) height; (6) weight (average, when in usual state of health; (7) circumference of the chest, on a level with sixth costo-sternal articulation, when momentarily at rest after an ordinary expiration, and also (8) after habitual natural expansion or inspiration (which last, usually exceeds the first measurement, expiration, by an increase of only about one-fourth of an inch); finally (9), the circumference after a *forced* expiration, and also (10) after a forced inspiration (these two measurements, 9 and 10, varying or showing a range of from one and one-half to four inches). The patient should, of course, be as calm as possible, and had better, usually, practice the *forced* breathing for a few acts before these two last measurements, 9 and 10, are taken.

To be of value all four measurements should be taken as carefully, accurately and free from haste as possible.

Any further information, in brief, as to degree of heredity (family history) in cases, prominent symptoms, loss in weight, cough, dulness on percussion, etc., or any remarks, will be a decided advantage.

Measurements of two cases, or several, or the average, could be given on one card.

With the hope that many will comply with the above request, and with much respect for and interest in the profession, I am,

Yours truly,

EDWARD PLAYTER, M.D.

"THE USE OF RINGER'S FLUID."

PHYSIOLOGICAL LABORATORY, HARVARD MEDICAL SCHOOL, BOSTON, March 6, 1897.

MR. EDITOR:—In reference to Dr. F. W. Johnson's paper in the *JOURNAL* of January 21st, page 52, and Dr. R. E. Edes's letter in the *JOURNAL* of March 4th, page 219, I would point out that the conditions to be fulfilled by artificial fluids as uninjurious as possible, within the limits of our present knowledge, to mammalian tissues were not all mentioned by Dr. Johnson (although I believe the solution used by him satisfied them), and are apparently not known by Dr. Edes. They are to be found summarily stated in the *Journal of the Boston Society of Medical Sciences*, No. 1, January, 1896 (this *JOURNAL*, Vol. CXXXIV, p. 173) where, it may be well to add, *isotony* is misprinted *isotomy*.

Truly yours,

F. S. LOCKE, M.D.

METEOROLOGICAL RECORD

For the week ending February 27th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 3,032; under five years of age 940; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping cough, erysipelas, diarrhæal diseases and fevers) 261, acute lung diseases 633, consumption 432, diphtheria and croup 85, diarrhæal diseases 43, whooping-cough 53, typhoid fever 30, scarlet fever 26, measles 25, cerebro-spinal meningitis 12, erysipelas 5.

From whooping-cough New York 12, Brooklyn 10, Baltimore and Washington 3 each, Chicago, St. Louis, Boston, Pittsburgh and Cambridge 1 each. From scarlet fever New York 17, Brooklyn 3, Boston 2, Pittsburgh, Cambridge, Malden and Everett 1 each. From measles New York 8, Chicago 7, Brooklyn 4, Boston and Worcester 2 each, Providence and Lynn 1 each. From cerebro-spinal meningitis New York 6, Worcester 2, St. Louis, Nashville, Cambridge and Medford 1 each.

In the thirty-three greater towns of England and Wales with an estimated population of 10,922,524, for the week ending February 20th, the death-rate was 18.8. Deaths reported 3,970; acute diseases of the respiratory organs (London) 355, whooping-cough 91, diphtheria 59, measles 55, diarrhæa 45, scarlet fever 40, fever 22, small-pox 1 (London).

The death-rates ranged from 13.7 in West Ham to 25.8 in Preston; Birmingham 21.0, Bradford 15.5, Bristol 17.5, Croydon 15.5, Gateshead 20.1, Hull 15.3, Leeds 20.0, Leicester 15.6, Liverpool 23.8, London 17.8, Manchester 22.3, Newcastle-on-Tyne 21.6, Nottingham 23.1, Sheffield 15.6.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE PERIOD FROM FEBRUARY 6 TO FEBRUARY 29, 1897.

MEAD, F. W., surgeon. Granted leave of absence for seven days from March 2, 1897.

BANKS, C. E., surgeon. Detailed for special duty on Ford's Theatre Commission. February 16, 1897.

KALLOCH, P. C., passed assistant surgeon. Granted leave of absence for four days from February 19, 1897.

WASDIN, EUGENE, passed assistant surgeon. Granted leave of absence for seven days from March 4, 1897.

KINYOUN, J. J., passed assistant surgeon. To proceed from Washington, D. C., to Havana, Cuba, for special temporary duty. February 15, 1897.

VAUGHAN, G. T., passed assistant surgeon. Detailed in charge of the Division of Sanitary Reports and Statistics of Bureau and attending surgeon, Port of Washington, D. C. February 24, 1897.

GEDDINGS, H. D., passed assistant surgeon. Detailed by the president as technical delegate to the International Sanitary Conference, to be held in Venice, Italy. February 12, 1897.

WERTENAKER, C. P., passed assistant surgeon. On being relieved from temporary duty at Philadelphia, Pa., about March 9, 1897, to rejoin his station at Delaware Breakwater Quarantine. February 27, 1897.

BLUE, RUFERT, assistant surgeon. Granted leave of absence for ten days from February 8, 1897. Upon expiration of leave of absence to proceed from New York, N. Y., to San Francisco Quarantine Station for duty. February 8, 1897.

OAKLEY, J. H., assistant surgeon. Granted leave of absence for thirty days from February 8, 1897. Upon expiration of leave of absence to proceed to Philadelphia, Pa., for duty. February 27, 1897.

NORMAN, SEATON, assistant surgeon. Granted leave of absence for ten days from February 8, 1897.

PROCHAZKA, EMIL, assistant surgeon. Upon being relieved from duty at Delaware Breakwater Quarantine, about March 10, 1897, to proceed to Reedy Island Quarantine for duty. February 27, 1897.

TABB, S. R., assistant surgeon. Granted leave of absence for fourteen days from March 10, 1897.

JORDAN, W. M., assistant surgeon. When relieved from duty at San Francisco Quarantine about March 1, 1897, to proceed to Marine Hospital, San Francisco, Cal., for duty. February 8, 1897.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

The next Thursday evening lecture will be given by ASST.-PROF. E. H. BRADFORD, on March 18th, at 8 P. M. Subject, "Disease of the Hip-Joint." The profession are invited.

SOCIETY NOTICES.

STEFFOLD DISTRICT MEDICAL SOCIETY.—The Section for Clinical Medicine, Pathology and Hygiene will meet at the Medical Library, 19 Boylston Place, Wednesday, March 17th, at 8 P. M.

*At 8 to 8.30: Short communications by Drs. J. M. Jackson, J. L. Morse and Vickery.

*At 8.30: Dr. Franklin W. White, "The Diagnostic Value of Tuberculin." E. W. TAYLOR, M.D., Secretary.

AMERICAN MEDICAL ASSOCIATION, FIFTIETH ANNIVERSARY.—The forty-eighth (there were no meetings held by the Association during the years 1861 and 1892) annual session will be held in Philadelphia, Pa., on Tuesday, Wednesday, Thursday and Friday, June 1, 2, 3 and 4, commencing on Tuesday, at 10 A. M.

Address: The Presidential Address, Nicholas Senn, Chicago; Address in Surgery, Wm. W. Keen, Philadelphia; Address in Medicine, Austin Flint, New York; Address in State Medicine, John B. Hamilton, Chicago.

Committee of Arrangements, H. A. Hare, 222 South 15th Street, Philadelphia.

WM. B. ATKINSON, Permanent Secretary.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

The programme of the Section in Surgery of the Twelfth International Medical Congress to be held at Moscow from the 19th to the 26th of August, 1897, is before us, and contains the titles of seven papers by European surgeons of eminence and the promise of seven other reports on surgical subjects. Fourteen special communications on subjects, the titles of which are not given, are promised, and nineteen gentlemen who have not promised communications have signified their intention of taking part in the work of the Section. A collective investigation into the merits of various anesthetics is being conducted, the completed report of which is to be presented at the Congress. The names of very few American, English or French surgeons appear on the programme.

RECENT DEATH.

THOMAS WOMESLEY, M.D., M.M.S.S., died in Watertown, March 7, 1897, aged eighty-one years.

BOOKS AND PAMPHLETS RECEIVED.

On Cyclone-Neuroses and Psychoses. By Dr. Ludwig Bremer, St. Louis, Mo.

Cooper Medical College, San Francisco, Annual Announcement, Session of 1897.

Original Articles.

TRICUSPID STENOSIS, WITH REPORTS OF THREE CASES WITH AUTOPSIES, TOGETHER WITH ABSTRACTS OF FORTY CASES REPORTED SINCE LEUDET'S THESIS (1888).

BY JAMES B. HERRICK, M.D., CHICAGO, ILL.,

Adjunct Professor of Medicine, Rush Medical College; Attending Physician to Cook County and Presbyterian Hospitals.

TRICUSPID stenosis is a cardiac lesion of such rarity that the finding of three cases within a few weeks is worthy of record. These were discovered in the morgue of the Cook County Hospital, August 12, August 30, October 21, 1896. The third case was seen by me during life. For the facts concerning the other cases I am indebted to the members of the house-staff of the hospital. In none of the three was an ante-mortem diagnosis of tricuspid stenosis made. The specimens were shown by me at the meetings of the Chicago Pathological Society for October and November, 1896.

CASE I. Female, age twenty-six. Rheumatic family history. Following childbirth, dyspnea, edema, cough, palpitation, for five months. Autopsy: tricuspid and mitral stenosis.

Cook County Hospital, Case 158,743. Admitted August 5, 1896. Discharged, dead, August 11, 1896.

Mrs. C. B., Austrian, twenty-six years of age. Had lived in this country seven years. Did general housework. Mother died in childbirth. Father died of heart disease following rheumatism. Three brothers and one sister healthy. No venereal taint in history or on examination. Denies scarlet fever or rheumatism. Measles at six. No miscarriages. Seven months ago gave birth to a healthy child, which she nursed for three months. Five months ago first noticed swelling of feet, shortness of breath, palpitation, pain in back, cough with frothy expectoration. Orthopnea for two months.

Examination showed her to be fairly well nourished; quite anemic. There was noted pulsation in vessels of neck (venous?); the breathing was hurried and there was inspiratory retraction of soft parts of the upper chest. The ankles and legs were edematous. The liver could be made out three fingers below costal arch, and showed slight systolic pulsation. Spleen palpable. No abdominal ascites. Lungs showed flatness and loss of vesicular sounds below seventh rib behind. Over the upper and resonant areas numerous moist râles, with intense respiratory sounds. Urine was pale, acid, 1020; small amount of albumin, hyaline casts.

In addition to the cervical pulsation and the hepatic pulse just referred to, the heart and vessels showed the following: "Dulness one-half inch to the right of the sternum in the second interspace, and extending in a vertical line till it is lost in liver flatness at the fifth rib. Absolute flatness begins on left side at fourth rib. Apex-beat in the fifth interspace one-half inch to left of nipple. It is weak. Over apex a thrill that is presystolic-systolic. Second pulmonary tone accentuated. Loud blowing murmur over apex, systolic, transmitted toward axilla. Also over xiphoid cartilage can be heard a loud systolic murmur. In this region a heaving impulse is plainly felt. There is no murmur heard in the carotids. The pulse is small and weak."

The patient entered the hospital August 5, 1896, and died August 11, 1896. The breathing remained embarrassed, averaging 36. There was an elevation of temperature to 100° on admission, and again for twenty-four hours preceding death, at which time it was 104.4°, axillary. At other times it was normal. The pulse was always weak, rapid and of such unstable quality that the nurse has several times placed an interrogation point after her record. Its average was 124.

Autopsy, August 12, 1896. Sixteen hours post-mortem. Condensing the record, there were found the following:

Heart, 560 grammes. Twice the size of owner's fist. Pericardium and coronaries negative. Marked hypertrophy and dilatation of both left and right ventricles. The same is true of the auricles, particularly the right. Aortic valves fairly competent to water-test; free edges very slightly thickened, with a few vegetations. Pulmonary semilunars show nothing abnormal. Mitral valves show marked thickening, especially toward the edges. The posterior cusp is largely adherent by its margin to the anterior, and seems practically immobile. The anterior cusp is more pliable. The opening is somewhat oval in shape, and admits but one finger-tip.

The tricuspid valves are attached by their margins, and form a ring that admits two finger-tips. The edge of this annular opening is surrounded by numerous easily removable vegetations. There was no defect of the ventricular or auricular septa. The aorta showed a few small atheromatous plaques.

Liver, 1,880 grammes. Showed changes of chronic passive congestion, macroscopically and microscopically.

Lungs. Edema, with numerous infarcts.

Spleen and Kidneys. Infarcts; slight increase of connective tissue in each organ by the microscope.

Clinical Diagnosis. Double mitral disease, with hypertrophy and dilatation of right and left hearts, relative tricuspid insufficiency, edema of lungs, passive congestion of liver and kidneys, hydrothorax and anasarca.

Anatomical Diagnosis. Mitral and tricuspid stenosis, with slight aortic sclerosis, infarcts in lung, spleen, kidney; passive congestion of liver and kidney; hydrothorax; general anasarca.

CASE II. Female, age twenty-four. Rheumatism at eighteen. Evidence of valvular disease two years later. Autopsy: Mitral stenosis, aortic regurgitation, tricuspid stenosis.

Cook County Hospital, No. 159,726. Admitted August 23, 1896. Discharged August 29, 1896.

D. A., female, single, Norwegian, age twenty-four, bookbinder by occupation. Gave a negative family history. Menstruation at seventeen. No evidences of previous pregnancy. Had rheumatism at eighteen. Two years later was told by a physician that she had heart disease. Several months ago was obliged to remain some time in bed on account of general weakness due to overwork.

August 19th, that is, four days ago, was forced to quit work on account of weakness. Overexertion causes pain over the lower portion of the chest. Gets out of breath easily; never faints; never has any headache, never any edema.

Present Condition. Fair flesh. Somewhat anemic. Tongue clean. Chest well developed. Movements

hurried and shallow. Lungs clear in front and behind. Abdomen and lower extremities negative.

Heart and Vessels. Pulse rapid, and counted with difficulty on account of feebleness of the same at the wrist. Relative dullness begins in third interspace in the right parasternal line and reaches to the left two fingers outside the nipple line. Absolute dullness begins in the fourth interspace in the left sternal line; reaches on the left to the mammillary line. Apex impulse visible, and palpable in fifth interspace two fingers outside of nipple line. Systolic murmur at apex transmitted into axilla. The breathing remained rapid during the patient's stay in the hospital, the temperature subnormal. The pulse at the wrist was usually uncountable; the heart's action was always rapid. Urinalysis showed neither albumin nor casts. The patient died suddenly at 6.15 A. M., August 29th.

Autopsy, August 30, 1896. Edema of lungs with infarct in right lung. Double hydrothorax with some old pleuritic adhesions. Chronic passive congestion of liver, spleen, kidney and intestines. Round ulcer of the stomach.

Heart very large, weighed 830 grammes. Over the right ventricle a thick layer of subpericardial fat. Coronaries negative. All the chambers of the heart enlarged. Walls of left ventricle greatly thickened, averaging nearly two centimetres. Excessive enlargement of right auricle. Muscular structure (*musculi pectinati*) of auricle shows great hypertrophy. Eustachian valve prominent. No defect in interventricular or interauricular septa; foramen ovale entirely closed by thick membranous curtain. Myocardium firm, a trifle pale. Aortic valves thickened and retracted; minute granulations on free borders. Smuses of Valsalva distended. Mitral valves thickened; cusps adherent, forming cone-shaped cavity at the apex of which, and toward the apex of the heart, is the circular opening that admits one finger-tip. Tricuspid leaflets united at margins in a manner similar to mitral. The circular orifice admits one and one-half finger-tips. The endocardium in the vicinity of the tricuspid and mitral valves is grayish and apparently deformed; the papillary muscles show the same change; the chordæ tendineæ are many of them shortened. Pulmonary valves negative.

The anatomical diagnosis of the cardiac lesion would therefore be mitral and tricuspid stenosis, aortic sclerosis permitting regurgitation, with general cardiac hypertrophy and dilatation.

CASE III. Female, age forty-six. Previous rheumatism. For months cough, dyspnea, edema, cyanosis, etc. Autopsy: mitral stenosis; tricuspid stenosis, *gradus levioris*.

Kate J., Case No. 157,962. Admitted July 20, 1896. Died October 18, 1896.

Patient is forty-six years of age, of average size. Had rheumatism some years ago. For months has complained of dyspnea, cough and palpitation. Is found on examination, cyanotic, dyspneic and edematous. Epigastric and cervical pulsation. Positive venous and hepatic pulse. Pulse irregular, small, rapid. Heart boundaries moderately enlarged, especially to right. Apical thrill, systolic and presystolic. At apex a systolic murmur. At most examinations, also, a presystolic or diastolic murmur; at times this murmur is inaudible. First tone at apex loud and abrupt; second pulmonic, accentuated. At first a

systolic murmur over tricuspid area; this later, with rest, disappeared, as did hepatic and venous pulse. At times delirium. Bleeding resorted to with temporary relief to dyspnea and cyanosis. Gradual failure. Death October 18, 1896.

Clinical Diagnosis. Mitral stenosis, with regurgitation; cardiac hypertrophy, with dilatation; relative tricuspid insufficiency; passive congestion of liver, spleen, kidney, stomach and intestines.

Autopsy (Dr. L. Hektoen). Chronic endocarditis of aortic, mitral and tricuspid valves (mitral and tricuspid stenosis); cardiac hypertrophy, dilatation of the auricles; thrombosis of right auricular appendix. Pulmonary edema. Right adhesive pleuritis. Passive congestion of the liver, with atrophy. Passive congestion of the kidney; chronic interstitial proliferation; old infarct in kidney. Chronic gastric catarrh. Ulcer in colon. Edema of extremities.

The heart weighed 370 grammes. There was comparatively little enlargement of the ventricular cavities or thickening of their walls. The auricles, on the contrary, were unusually dilated, particularly the left. The pulmonary valves were negative. The aortics show a little fibrous thickening, but were fairly competent to the water-test. The mitral cusps were thickened and adherent, the opening admitting two finger-tips; a few small, fresh vegetations upon their edge. The tricuspids showed a slighter degree of stenosis, just admitting three finger-tips. The aorta had a few yellowish plaques at its beginning.

FREQUENCY.

Walsh says "excessively rare," and the least common of lesions. Strümpell says "so rare as to have no practical significance." Ashton¹ in 1,024 clinical diagnoses of valvular disease found no tricuspid stenosis. In St. Mary's Hospital, London, from 1851-1870, there was found but one case of tricuspid stenosis.² But in 1868 Duroziez found records of 21 cases. Bedford Fenwick in 1881 analyzed 46 cases; and in 1888 the younger Leudet, in a Paris thesis, collected 117 cases, 114 of which were with autopsy records. Since Leudet, I find 40 cases with autopsies, making a total of 154. Leudet's thesis must furnish the foundation for future work, and I freely quote his statements.³ Since then several cases have been added to the list, but little has been added to change his conclusions.

CLASSIFICATION.

Tricuspid stenosis may arise as the result of intra-uterine endocarditis or myocarditis, or as an intra-uterine fault of development; or it may be post-natal and the result of an extra-uterine endocarditis. From these facts arise the common classification into congenital and acquired cases.

CONGENITAL TRICUSPID STENOSIS.

This form, the result of a developmental vice or an intra-uterine endocarditis, is generally accompanied by some of the following abnormalities: stenosis of the pulmonary artery, defects in the interventricular septum, patent foramen ovale and ductus Botalli. Clinically these cases present the phenomena of cyanosis, clubbed fingers, diastolic and systolic bruits. Few survive until twenty, succumbing to circulatory dis-

¹ Medical News, 1894, No. 25.

² Hay: Medical Record, September 7, 1889.

³ In Leudet's thesis a complete bibliography up to 1888 is to be found.

turbances or to an intercurrent tuberculosis. It is not my purpose further to discuss the congenital forms.

ACQUIRED FORM.

Etiology.—Antecedent rheumatism was found by Leudet in about 50 per cent. In the 151 cases, 51, that is, 30 per cent., had rheumatism. This is more than 50 per cent. of the cases where rheumatism is referred to. (See Table IX.)

Leudet, Fenwick, Duroziez, Baumel, are firm believers in the rheumatic origin. Leudet believes that under this head should be classed the milder manifestations of rheumatism, such as sore throat, muscular rheumatism, etc. Some, however, as Peacock and Rosenstein, regard all cases of tricuspid stenosis as of congenital origin. Flint speaks of an acquired tricuspid stenosis as a rare curiosity; Niemeyer as exceptional; Skoda never saw a case in the living. The view that rheumatism may be an extra-uterine cause is supported not alone by the absence in many cases of symptoms of cyanosis in childhood, the age of some of the patients, the clear history of rheumatism with cardiac symptoms soon following, as in my own case (11), but by the absence of the almost inevitable consequences of intra-uterine right-heart valvular obstruction, namely, patent foramen ovale and ductus arteriosus or deficient septum. Syphilis has been assigned as a cause. Leudet believes the puerperal state explains its greater frequency in women (compare Case 1). Auriculo-ventricular disease, it may be noted, is commoner in women (Bamberger). Of Leudet's 114 cases, 86 were women, 22 men, 6 sex not recorded. The age at death showed the largest number, 38 per cent., dying between twenty and thirty. The youngest to succumb died at fourteen, the oldest at sixty-four. Adding the cases I have collected, I find out of a total of 154, 114 in women, 32 men, 8 sex not recorded. The youngest case is that of Colbeck, a boy, dying at twelve. As in Leudet's series, the largest number died between the ages of twenty and thirty. (See Tables II and VII.)

Pathological Anatomy.—The tricuspid leaflets are commonly found adherent by their free borders. They may be more or less thickened. The neighboring endocardium may show inflammatory change in the grayish, fibrous areas; the chordæ tendineæ may be shortened, the papillary muscles deformed. The opening, linear, oval or circular, is at the base of a cone made of the united cusps and may admit three finger-tips, two, one, or less than one. The latter cases, Bamberger says, merit admission to anatomical museums. These changes are the result of an endocarditis that has been graphically described by Chauffard as follows: "This is the result of a chronic endocarditis that is slow and silent, generalized rather than profound, very slightly vegetative, but rather adhesive and plastic, and that tends to unite the diseased valves by their borders." Vegetations and calcareous plaques may be found. One of Leudet's own cases was an ulcerative endocarditis implanted on tricuspid valves, the site of an old stenosis.

Leudet makes a second class of cases including the stenoses, strictly speaking, and a third class where the obstruction is due to polypoid concretions, vegetations, etc. Symptomatically these are stenoses; pathologically, in a strict sense, they are not.

Tricuspid stenosis is rare as an isolated valvular lesion. Naturally with the stenosis there is regurgita-

tion at this orifice. Other valves are commonly involved. Only 11 of Leudet's cases showed tricuspid disease alone. Many older writers claim that tricuspid stenosis never occurs without lesions of the left-heart valves, and this statement is not uncommonly met with in recent text-books. Leudet's statistics, however, disprove this. His table is as follows:

Tricuspid stenosis alone	11
Tricuspid stenosis with mitral stenosis	78
Tricuspid stenosis, mitral and aortic stenosis	21
Tricuspid stenosis and pulmonary stenosis	3
Tricuspid stenosis, mitral stenosis and pulmonary stenosis	1
	<hr/> 114

For completed table see Table VII.

Usually the mitral is more contracted than the tricuspid, as in my three cases. It is exceptional to find the right auricle of normal size (Hayden, Duroziez). Commonly it is enlarged; it may be truly colossal, three times its normal size, and like "a supplemental heart." Where the stenosis has been marked, there has been found a small right ventricle, and this in spite of the fact that there may be mitral stenosis (Cf. Case 11). Commonly, however, the combined lesions give general enlargement of the heart chambers, as in the first two of my cases. A patent ductus arteriosus has been found. Ashton calls attention to the fact that no cases are reported where tricuspid and aortic stenosis have been combined without there being an associated mitral stenosis.

SYMPTOMATOLOGY.

The subjective symptoms are those common to valvular diseases. Dyspnea may be extreme. Cyanosis is generally marked. Venous stasis with edema may be pronounced. The pulse, from small supply of blood to the systemic side of the heart, is small, the pulmonary tone commonly feeble. Venous pulse, presystolic in character, is generally seen, often with a positive systolic pulse from concomitant insufficiency. Percussion reveals an enlarged right heart and commonly left also, from mitral or aortic disease. In Case I the high point (second space) at which dullness began to the right of the sternum, would be suggestive of right auricular enlargement. Thrills are at times present.

The murmur is diastolic, heard best over the tricuspid area and is particularly diagnostic when clear-st over the right fifth and sixth cartilages (Grawitz). The murmur is frequently inaudible. Frequently, too, the presence of other murmurs, or of adventitious pulmonary and bronchial sounds, serves to drown the murmur of this lesion; or tachycardia and arrhythmia make its analysis impossible. That there is no uniformity in the character, intensity, quality, or even presence of the murmur is shown by the diverse testimony of competent observers. To quote only a few who speak of it: Hope says the murmur is a rarity. Walshe knew nothing of it by experience, though thinks he heard one such murmur. Sieveking says it is theoretical but never met. Berth and Roger, Potain and Rendu says it has never been proven. Paul says the same thing. Flint says a "tricuspid direct murmur is one of the rare curiosities of medical experience." Leube says the symptoms are largely theoretical. Da Costa says the same. So rare is this form of valvular disease that Skoda advised that a diastolic murmur over the right ventricle be rather looked upon as pericardial. The murmur in Shattuck's

case was for a long time absent. In some of Colbeck's cases he records a "suspicion of a murmur."

But six of the 114 cases were diagnosed during life. Since then Shattuck⁴ reports an ante-mortem diagnosis in which a double murmur in the tricuspid area so differed from that heard over the mitral region that the tricuspid was believed to be affected and was so proven post-mortem. Grawitz also made an ante-mortem diagnosis. Duroziez says the tricuspid murmur is audible only in front. Hayden found an area between the mitral diastolic and the tricuspid diastolic where no murmur was heard, hence proving two murmurs. Many other records, for example, Stokes, Haldem, Duroziez, Charteris, Fenwick, Duckworth, and others, show a diastolic murmur. Some of Colbeck's series were diagnosed *intra vitam*.

DIAGNOSIS.

To judge from the clinical histories of the cases reported, one may conclude that tricuspid stenosis can be suspected when the patient is a female; has had rheumatism; has a history of dyspnea, palpitation, edema, often with remissions and exacerbations; is cyanotic; has rapid, arrhythmic, feeble pulse; has mitral stenosis with enlarged right heart, particularly if auricular enlargement can be made out. Especial value attaches to persistent cyanosis. If, in addition to this, there is a presystolic or diastolic murmur, heard best over the ensiform, or over the right fifth and sixth cartilages, and particularly if this murmur differs in intensity, quality, or pitch from the mitral diastolic, or if there is an area between the mitral and tricuspid areas where no murmur is audible, the diagnosis becomes reasonably certain.

Theoretically, enlarged right heart, feeble pulmonary second sound, diastolic murmur over the tricuspid area, loud right-heart tones, marked cyanosis and weak pulse would be expected in tricuspid stenosis. Its combination with other valvular lesions makes its recognition extremely difficult in practice. One does well if he suspects it. Probably the most certain sign is the diastolic murmur over the xiphoid differing in quality from that heard over the mitral area, such as was heard in Shattuck's case. But this is inconstant.

Colbeck adds that a short, sharp, and loud right-heart first sound not obscured by a systolic murmur that may be present, points toward tricuspid stenosis. Shattuck's conclusion is that, "Whether a presystolic soufflé can be heard or not, tricuspid stenosis can be pretty safely diagnosed if the patient is a female with rheumatic history, has mitral stenosis, perhaps also aortic disease, and presents the evidences of prolonged or recurrent venous stasis of greater or less degree." The occurrence of serious dropsy in mitral stenosis is, according to Sir William Broadbent (quoted by Colbeck), an evidence of tricuspid stenosis.

PROGNOSIS.

While the prognosis is in general bad, the fact that patients may live for years, even to the age of sixty-four, should be remembered. We commonly, too, hear auricular compensation spoken of as purely theoretical. A glance at the greatly thickened wall of the right auricle in the specimen from my own case (11), with the massive *musculi pectinati*, will convince one that the auricular hypertrophy in this case at least, must have rendered the right auricle, for a

time, competent. The prognosis must be determined by the complexus of symptoms, the general condition of the patient, the nature of the occupation, etc. The relief to, or the prevention of, pulmonary congestion offered by tricuspid stenosis ought, perhaps, to be taken into account as explaining the ripe age attained by some of these patients.

TREATMENT.

This would be governed by the same rules that govern the treatment of cardiac valvular disease.

ABSTRACT OF CASES SINCE LEUDET'S THESIS (1888).

CASE 1. Hebb, R. G. "The Westminster Hospital Reports," 1888. Vol. IV, p. 183. Post-mortem records only are given. Male, age nineteen. Admitted December 1, 1884, under Mr. Cowell; died February, 1885.

Autopsy. Terminal phlegmonous erysipelas. Pericardial fluid. Auricular hypertrophy and dilatation; ventricles small. "Both auriculo-ventricular valves are in the condition of extreme stenosis. The aortic orifice is also stenosed."

CASE 2. Hebb, *ibid.* Female, age thirty-two. Admitted April 27th, under Dr. Donkin; died June 18, 1885.

Autopsy. Heart 14 ounces. Both auricles enlarged and their walls hypertrophied. "There is stenosis of the tricuspid and mitral valves, the latter not admitting the tip of the little finger. The tricuspid measures just three inches. The cusps of all four valves are bestudded with recent delicate vegetations."

CASE 3. Hebb, *ibid.* Female, age forty. Admitted July 12th, under Dr. Allchin; died July 16, 1888.

Autopsy. Heart 12 ounces. Auricles large. Right auriculo-ventricular orifice just admits the tip of forefinger; cusps adherent. Mitral orifice "a mere chink"; cusps adherent. Ventricles small. Aortic valves slightly thickened but competent.

CASE 4. Hebb, *ibid.* Female, age twenty-three. Admitted under Dr. Allchin; died September 24, 1887.

Autopsy. Heart 17 ounces. Auricles dilated. Mitral and tricuspid valves are stenosed from thickening and adhesion of the cusps.

CASE 5. Hebb, *ibid.* Female, age forty-one. Admitted April 24, 1885, under Dr. Sturges; died September 28, 1887.

Autopsy. Heart 16 ounces. Cusps of mitral and tricuspid adherent and thickened. Aortics slightly thickened at bases. Mitral 2.0 inches; tricuspid 4.25 inches.

CASE 6. Hebb, *ibid.* Female, age twenty-six. Admitted September 15, 1885, under Dr. Sturges; died October 31, 1887.

Autopsy. Heart 13½ ounces. "The cusps of the mitral and tricuspid are adherent and thickened." Tricuspid ring 3.0 inches; mitral 1½ inches.

CASE 7. Hebb, *ibid.* Female, age sixty-three. Admitted April 2d, under Dr. Donkin; died May 14, 1888.

Autopsy. "Heart 14 ounces. Tricuspid thickened and its two anterior cusps united by an opaque cicatrix. Aperture 4.5 inches. The cusps of the mitral are thickened and adherent and its aperture linear; 1.8 inches."

CASE 8. R. G. Hebb. "Transactions Pathologi-

⁴ Boston Medical and Surgical Journal, March 26, 1891.

cal Society," London, XL, 60. Female, A. V. At eighteen treated for heart disease. Dyspnea for long time previous. No acute disorder. In 1886 hemiplegia (embolic). Cardiac enlargement, arrhythmia, presystolic thrill and murmur. Died at age of twenty-three, February 1, 1889.

Autopsy. Heart $13\frac{1}{2}$ ounces; mitral and tricuspid stenosis; auricular hypertrophy; some recent inflammation of endocardium of wall of left auricle.

CASE 9. Hay, C. M. *Medical Record*, September 7, 1889, xxxv, p. 256. Woman, age thirty-five. Mania, marked cyanosis, arrhythmia, feeble pulse, and feeble apex-impulse, systolic thrill. Murmurs difficult to analyze, but double mitral and double aortic recorded. Jaundice, temperature 102° , gangrene of nose.

Autopsy. Congestion of brain, lungs, kidney, liver, spleen; old pleuritis. Heart: hydropericardium; aortic stenosis (less than one finger-tip); mitral stenosis (one finger-tip); tricuspid stenosis (two finger-tips); auricles greatly hypertrophied and dilated; ventricles but little changed; no septal defects.

CASE 10. Vaughao, J. S. C. *Medical Press and Circular*, London, 1889, n. s., XLVIII, p. 80. Not accessible, quoted from Ashton's table.

Female, age twenty-six. No rheumatism; tricuspid and mitral stenosis; aortic vegetations.

CASE 11. Vaughan, *ibid.* Female, age fifty. No rheumatism. Tricuspid and mitral stenosis, with aortic vegetations.

CASE 12. Pawinski. *Gazeta lekarska*, 1890, No. 26. Abstract in Virchow and Hirsch's *Jahresbericht*. Female, age thirty. No mention of rheumatism. Cardiac enlargement. Apical double murmur. Pulmonic second accentuated. Death from intercurrent pneumonia and meningitis.

Autopsy. Tricuspid, mitral and aortic stenosis. Ventricles not enlarged; auricles greatly dilated.

CASE 13. Thacher. "Proceedings New York Pathological Society," *Medical Record*, 1889, xxxv, p. 189. Female, age twenty-nine. No rheumatism; scarlatina in childhood. For five months edema and dyspnea. Congestion of the face. Heart enlarged, irregular. Mitral presystolic and aortic direct murmurs.

Autopsy. Tricuspid, mitral and aortic stenosis.

CASE 14. F. C. Shattuck. *Boston Medical and Surgical Journal*, CXXIV, p. 307. H. G., female, age forty-three, seamstress, alcoholic. Admitted February 19, 1886. Doubtful history of rheumatism in 1871. In 1879 was told she had heart disease. Repeated attacks of cough, asthma, dyspnea, dropsy.

Examination showed cardiac dullness, increased especially to the right. Hepatic pulse. Over aortic, mitral and tricuspid areas, double murmurs. "The systolic and presystolic murmurs in the tricuspid area can be differentiated from those in the mitral area, their qualities being different, and the tricuspid presystolic distinctly musical." Diagnosis of tricuspid stenosis made ante-mortem. "Under treatment dropsy disappeared as did also the presystolic tricuspid murmur, and I never heard this again." For two years spent part of her time in hospital and part at her work. Died, May 3, 1890. Clinical diagnosis: Mitral and tricuspid stenosis and regurgitation; aortic regurgitation and stenosis or roughening; adherent pericardium; hepatic cirrhosis, slight interstitial nephritis.

Autopsy. (Dr. Fitz.) Confirmed diagnosis of val-

vular lesions. Mitral admitted less than one finger; tricuspid admits two finger-tips; aortic incompetent; slight and more recent vegetations on pulmonary valves; small aortic aneurism at beginning of arch.

CASE 15. E. Grawitz. *Zeitschrift für klinische Medicin*, Vol. xxiii, p. 168. Case of a man, twenty-four years old. St. Vitus's dance, when a child, for five years. Symptoms of valvular heart disease. Ante-mortem diagnosis of tricuspid stenosis. Autopsy showed aortic, mitral and tricuspid stenosis. The wall of left ventricle very thin. In diagnosis he regards murmur over fifth right cartilages as of great value. In this case with "thud" also.

CASE 16. Delépine. "Transactions Pathological Society," XLII, p. 59. Male, age forty. Old stricture. Repeated attacks of hematuria dating back six years. Five weeks before death, rupture of "anal abscess."

Autopsy. Tricuspid cusps thickened and partly calcified with thick and calcified vegetations. Fibrous thickening and calcification of endocardium of left auricle.

CASE 17. Drummond. *Lancet*, September 10, 1892. Aortic, mitral and tricuspid stenosis in a woman forty years of age. The tricuspid murmur thought to be transmitted. The case is believed by Drummond to be congenital.

CASE 18. Chaplin. "Transactions Pathological Society," London, 1892, XLIII, p. 29. Girl, age eighteen. Dyspnea, edema, cyanosis. Cardiac enlargement. Apical systolic and presystolic murmur. Death in eight days, preceded by hemoptysis. No rheumatic history. Scarlet fever eleven years ago.

Autopsy. Extreme stenosis of mitral and tricuspid valves. Aorta narrow. Regarded as possibly congenital.

CASE 19. Chaplin, *ibid.* Age and sex not given. Distinct history of rheumatic fever. Autopsy showed mitral stenosis and tricuspid stenosis (two finger-tips).

CASE 20. Philip. "Edinburgh Hospital Reports," 1893, Vol. I. Male, age forty-six. No rheumatism. Simple tricuspid stenosis (quoted from Ashton).

CASE 21. Gibson. "Edinburgh Hospital Reports," 1893, Vol. I. Female, age thirty-one. Rheumatism. Tricuspid and mitral stenosis.

CASE 22. Gibson, *ibid.* Female, age twenty-one. No rheumatism. Tricuspid and mitral stenosis.

CASE 23. Colbeck. *Medical Chronicle*, Manchester, 1893, xviii, pp. 297-312. Thesis for degree M.D., Cambridge. John T., age forty-four. Service of Dr. Broadbent, admitted February 24, 1892. Rheumatism at fourteen. Dyspnea, edema, moderate cyanosis, albumin, pulse 90. Heart enlarged, right and left. Apical first sound loud and abrupt; second sound faint. Presystolic thrill and presystolic murmur. Systolic murmur over tricuspid.

Autopsy. Tricuspid admitted two fingers; mitral, one finger.

CASE 24. Colbeck, *ibid.* Kate M., age thirty-two. Admitted December 1, 1891, under Dr. Lees. No rheumatism. Dyspnea for six months; edema, distended veins. Pulse small, 120. Heart enlarged in all directions. Systolic apical murmur; also long, rumbling presystolic murmur, leading up to a very loud snap synchronous with impulse. Second sounds feeble. December 16th, suspicion of presystolic murmur over ensiform.

Autopsy. Great hypertrophy of right auricle. Tri-

cuspid admits one finger. Mitral same. Cavity of left ventricle contracted.

CASE 25. Colbeck, *ibid.* Fanny R., age thirty-eight. Admitted January 6, 1892, under Dr. Broadbent. Cough, dyspnea, hemoptysis. History of rheumatism. Marked cyanosis. Pulse small, irregular, 100. A presystolic murmur heard best over the ensiform differed from a synchronous murmur heard over apex.

Autopsy. Mitral and tricuspid stenosis, each admitting one finger-tip.

CASE 26. Colbeck, *ibid.* E. H., female, age thirty. Admitted May 30, 1887, under Sir Wm. Broadbent. Rheumatism eight years before. Cyanosis, clubbed fingers, dyspnea; pulse, 132, irregular, weak. Toward the last a presystolic murmur was heard over the ensiform. "June 24th, a diastolic murmur was heard at the apex, and a presystolic murmur in the tricuspid area."

Autopsy. Tricuspid and mitral stenosis, each one finger-tip.

CASE 27. Colbeck, *ibid.* John L., age twelve. Case of Mr. Lunn. Rheumatism two years before. Edema, palpitation, cough, cyanosis, venous pulse. Toward the last a short, rough, presystolic murmur was heard.

Autopsy. Mitral and tricuspid stenosis (one finger-tip). Pulmonary cusps slightly thickened.

CASE 28. Colbeck, *ibid.* Margaret S., age eighteen. Case of Dr. Sansbury. Probable rheumatism six years before. Edema, dyspnea, cyanosis; pulse 120, regular. Heart enlarged, upper limit to second rib. Systolic and presystolic apical murmurs.

Autopsy. Tricuspid and mitral stenosis (one finger-tip).

CASE 29. Colbeck, *ibid.* Alice R., age twenty-five. Case of Dr. Eustace Smith. Rheumatism at fourteen. Dyspnea, edema, clubbed fingers; pulse 60 and small; systolic and diastolic murmurs at apex.

Autopsy. Tricuspid, two fingers; mitral, one finger.

CASE 30. Colbeck, *ibid.* Man. Dropsy, cyanosis, dyspnea. Presystolic apical murmur and accentuated right-heart sounds.

Autopsy. Mitral stenosis, with thickening of tricuspid flaps and some narrowing of orifice.

CASE 31. Colbeck, *ibid.* Woman, same as in Case 8, with suspicion of diastolic murmur in tricuspid area.

Autopsy. Tricuspid and mitral stenosis.

CASE 32. Müller. *D. Militärärztl Zeitschrift*, Heft 1, 1894. Case where rheumatism existed for twenty years before. Aortic, mitral, tricuspid disease, and pericardial adhesions.

CASE 33. Middleton. *Glasgow Medical Journal*, April, 1894. Female, age forty-four. No rheumatism; scarlet fever in childhood. Symptoms of cardiac disease for eight years. Admitted to Glasgow Infirmary, May 2, 1893. Palpitation, dyspnea, edema, ascites, cyanosis. Repeated tapplings for ascites. Cardiac dullness greatly increased to right and left; shape and area suggestive of pericardial effusion. Apical thrill. Auricular-systolic and ventricular-systolic murmurs. Systolic murmur over aortic cartilage. Venous pulse; pulmonic congestion not marked. Possibility of tricuspid stenosis discussed.

Autopsy, November 28, 1893. Heart greatly enlarged, 17 ounces. Right auricle enormously distended, and producing greater part of dullness to the right of

sternum. Aortic, mitral and tricuspid stenosis. Mitral circumference $1\frac{1}{2}$ inches; tricuspid 2 inches.

CASE 34. Ashton and Stewart. *American Journal Medical Sciences*, 1895, n. s., cix. Male, age nineteen. Influenza at fifteen. No definite previous rheumatism, though "rheumatic pains." Dyspnea, palpitation for four to six years previous. Heart lesion (mitral stenosis) recognized during examination for life insurance in March, 1894. A few weeks later, increasing dyspnea, marked cyanosis, edema. Examination showed enlarged heart, with feeble impulse. Pulse at wrist imperceptible. Presystolic apical thrill; none over tricuspid area. Apical presystolic and systolic murmurs. Systolic murmur also over tricuspid area and over aortic cartilage. Clinical diagnosis of double mitral lesion with relative tricuspid insufficiency.

Autopsy, July 28, 1894. Hydropericardium, enlargement of chambers of right heart; pronounced stenosis of tricuspid, mitral and aortic valves.

CASE 35. Dock. "Transactions Association of American Physicians," 1896, Vol. xi, p. 186. Male, age twenty. Always weak and sickly. Chorea at eight years; scarlatina at twelve; influenza also. Face was "blue" at sixteen. Several times in hospital under Dr. Dock, with evidences of compensatory failure. Heart greatly enlarged to left and right. Apical diastolic murmur and presystolic thrill, flapping first sound, pulmonic second accentuated. Pulse irregular and quick. Later an apical systolic murmur and systolic musical murmur over ensiform. *Pulsus celer*, and loss of aortic second tone. Thrill also felt in second interspace to right of sternum. Cyanosis always pronounced. Never a positive venous pulse. Liver at first enlarged, later smaller. Numerous tapplings for ascites. Diagnosis of double mitral lesion, aortic insufficiency, tricuspid regurgitation. Possibility of congenital defect or tricuspid stenosis considered.

Autopsy. Tricuspid, mitral and aortic stenosis. Atrophic liver (cardiac).

CASE 36. Balfour. Quoted from Ashton and Stewart. Male, age fourteen. No rheumatism. Tricuspid and mitral stenosis.

CASE 37. Herrick, James B. Current number of this journal. Female, age twenty-six. Rheumatic family history. Two months after childbirth and five months before coming under observation, noticed edema, cough, dyspnea, palpitation, slight albuminuria. Patient was edematous, dyspneic and cyanotic. Jugular and hepatic pulse. Heart universally enlarged especially to right and upwards. Systolic murmurs over apex and xiphoid. Presystolic thrill at apex. Accentuated pulmonic second. Pulse small, rapid, irregular.

Autopsy. General hypertrophy and dilatation of all heart-chambers, particularly right auricle. Septa intact. Tricuspid stenosis (two finger-tips); mitral stenosis (one finger-tip); some thickening of aortic cusps, with a few vegetations.

CASE 38. Herrick, *ibid.* Female, age twenty-four. Rheumatism at eighteen. Evidences of valvular disease two years later. Dyspnea, but no edema. Heart generally enlarged. Apical systolic murmur. Further findings uncertain because of rapid heart action.

Autopsy. Heart greatly enlarged in all its chambers. Right auricle shows excessive hypertrophy and

dilatation. No defect in septa. Tricuspid and mitral stenosis with aortic insufficiency.

CASE 39. Herrick, *ibid.* Female, age forty-six. Previous rheumatism. For months cough, dyspnea, edema and cyanosis. Pulse small, irregular, rapid; positive venous pulse; hepatic pulse. Moderate cardiac enlargement. Presystolic and systolic thrills. Double mitral murmur. Systolic murmur over tricuspid area. Snappy first tone; second pulmonic accentu-

ated. Tricuspid murmur, venous pulse and presystolic murmur not constant. Venesection for extreme cyanosis. Gradual failure. Clinical diagnosis: double mitral disease, with relative tricuspid insufficiency.

Autopsy. Tricuspid and mitral stenosis, with slight thickening of aortic cusps.

CASE 40. Lipari. *Rif. med. Napoli*, 1891, vii. From file in "Index Medicus." Tricuspid and mitral stenosis with *concretio cordis*.

* I have been unable to consult this article either in the original or in abstract. The title, however, is so full as to enable it to be included in the list. Five or six other references that I have been unable to verify are omitted from the list, though undoubtedly three or four of them should be included.

In tabular form these forty cases show the following summary :

I.—SEX.	
Male	10
Female	28
Not mentioned	2
	40
II.—AGE AT DEATH.	
10 to 20 years	6
20 to 30 years	11
30 to 40 years	7
40 to 50 years	9
50 to 60 years	1
60 to 64 years	1
Not mentioned	5
	40
III.—PREVIOUS HISTORY.	
Rheumatism	10
Chorea	2
Doubtful rheumatism	4
No rheumatism	9
Not mentioned	15
	40
IV.—VALVULAR LESIONS.	
Tricuspid alone	1
Tricuspid and mitral	18
Tricuspid and pulmonary	0
Tricuspid, mitral and aortic	18
Tricuspid, mitral and pulmonary	1
Tricuspid, mitral, aortic and pulmonary	1
Tricuspid and endocardium of left auricle	1
Tricuspid and aortic	0
	40

In the class tricuspid, mitral and aortic are included all cases in which the aortic valves are recorded as "slightly thickened," "thickened," "with vegetations," etc. In ten of these cases the lesion is described as aortic stenosis.

Combining Leudet's series with my own, the following figures are obtained :

V.—TOTAL NUMBER OF CASES WITH AUTOPSY.	
Leudet	114
Herrick	40

THE PSYCHICAL NERVE-CELLS OF TWO EDUCATED MEN.

BY HENRY J. BERKLEY, M.D., JOHNS HOPKINS UNIVERSITY, BALTIMORE, MD.

It is more for the purpose of showing what results can be attained in pathological psychiatry under exceptionally good circumstances, than for positive ones that we present the following cases. The first I consider a standard, a control for future guidance; for in other researches upon human material obtained from the clinic on mental diseases, I have been largely influenced by the doubt, in using the silver methods of staining, if in some instances we were not recording post-mortem, and not pathological alterations.

A rather abundant supply of cerebral tissues, normal and pathological, has led me to the conclusion that the lateral buds on the dendritic twigs are the first portion of the cell to show after-death alterations; and as their relation to the terminal apparatus of the nerve fibres of the cortex is most, indeed in the first degree, important, it may be readily seen that it is necessary to have our material for the newer methods of brain-cell staining of immaculate freshness. Very seldom indeed have the gemmules of the psychical cells shown the same degree of luxuriance, in cases in which the autopsy has been performed eighteen or twenty hours after death, as when it has been made within five, or at the utmost six hours, or, before the bodily heat has entirely disappeared.

Most prominent among the alterations found in all cases of chronic insanity have been departures from the normal in the gemmule; the bodies of the cells may retain their usual form, the branches may be quite as extensive and widespreading as they are in the control preparations, but the delicate round-headed processes are affected in some manner, usually in the acquired mental reductions by an extensive shading of the buds, and in the different forms of idiocy by various defects of development, evidenced in their greater length and sparser numbers than in the normal brain. Like other late developed portions of cellular protoplasm, the lateral buds are the first to show decay and degenerescence when the strain of unwonted conditions is thrown upon their structures.

The subject of our first investigation was a man of not profound mental endowments, and with a decidedly greater tendency to "sharpness" than depth. He began his business life as a drug clerk, and afterwards obtained the degree of doctor of medicine from a respectable school; but obtaining few clients, lived in great poverty. He was a moderate, but so far as could be ascertained, never a heavy drinker. Finally he became involved in various intrigues, and eventually poisoned a woman to obtain her money. For this crime he was electrocuted, and an autopsy performed immediately after the execution. The various portions of the cortex obtained, were fixed in Müller's fluid, and were afterwards stained according to the silver phospho-molybdate formula.

The autopsy showed the cadaver of a well nourished man of medium height. The brain was below the average weight, but was macroscopically normal. The thoracic and abdominal viscera were healthy.

An examination of the psychical nerve cells of the cortex of this physician showed a degree of individual development that was surprising (Figs. 1 and 2). This development lay not in the number and size of the neurons, which were not more numerous stained

than customarily, but in the development of the dendritic branches and their adherent gemmules. The dendrites are stouter and broader than in any brain we have hitherto met with, and the lateral buds issuing from their sides are far more numerous than ordinary, and surpass in closeness of setting on the stem, in stoutness and in length, those upon the pyramidal cells of animals that have had their almost living tissues fixed in a similar bichromate preservative fluid, and stained by the same method.

Each of the gemmulæ stands forth from the protoplasm of the dendrite with surpassing sharpness, and shows the round-headed arrangement seen in all the higher mammals. The intermediary and other pluripolar cells do not show the same differences between this perfectly fresh brain and others obtained from cases in which the post-mortem was obtained at a later hour. Their branches were, of course, free from gemmulæ of the type belonging to the psychical cells,

FIG. 1.

FIG. 2.

FIG. 3.

but showed the usual irregular thorns upon the stems. Very few indeed of the psychical cells showed other than absolutely normal characteristics. In the dozens of sections made, not more than five or six cells with swollen and knotted dendrons, and with the gemmulæ absent over the site of the thickenings, were found — a proportion so inconsiderable as almost to be passed over without comment, and enable one to determine that the brain was almost histologically sound. What little damage there was present could be reasonably referred to the alcoholic abuse in the years antedating his long imprisonment for the crime of murder.

The appearance of the nerve fibres is absolutely normal; numerous axons and collaterals were stained, but nowhere was there any departure from natural conditions.

The different forms of the neuroglia cells show exactly the same forms and dispositions that we would be led to expect from the previous examination of adult animals, nor do the peculiar endings of the cells upon the outer margins of the blood-vessels' channels present any notable differences.

The second cortex examined came from the brain of

a medical man of vastly greater mental endowments than the first, and who had graduated at the Royal University of Ireland and at Edinburgh. Never very steady in his habits, his career, at first brilliant, soon became erratic. He became addicted to opium and alcohol, and soon began to drift downward in the social scale. In his forty-fourth year he landed in the United States, and commenced to practise medicine in a Northern city. He resumed his evil habits, and five years later found him in a House of Correction. Now he was adjudged to be insane, and was transferred to the Baltimore City Asylum.

The immediate family history showed that the mother died of cancer, and that the father lived to an advanced age. There is a sister living who is deformed. Patient has never acquired syphilis.

On his admission to the institution he was somewhat excited, talkative, with numerous delusions of a

personal nature, such as being a great pugilist, a great artist, that he was filled with electricity, and could move great bodies by this force with little effort.

These delusions varied considerably from day to day. There were also some vague aural and visual hallucinations. The mental reductions were considerable. The reflexes of all kinds were normal. There was slight tremor about the hands, of an alcoholic type, readily controllable. The skin over the body was slightly hyper-sensitive. A physical examination showed advanced tuberculosis of the lung apices.

The patient gradually sank, physically and mentally; he became untidy, and the delusions became less vivid. No apoplectic crises occurred. Tubercular enteritis finally ended the scene six months after admission.

The autopsy (eight hours after death) showed extensive tubercular disease of the lungs, pleura, intestines and lymphatic apparatus. The brain was slightly atrophied, and covered with a thin layer of gelatinous lymph. The fissures and convolutions showed no anomalies. The skull was regular, brachycephalic, and of moderate thickness.

Between this brain and the foregoing one the cortical cells show wide variation, both in size and general appearance. Care was taken to make the several regions from which the sections were taken correspond with those of the first brain, in order to have under view cells of approximately similar function. The hardening and staining were precisely similar for both brains.

The differences between the cells consisted mainly in a diminution of the transverse diameter of the dendrites, as well as in the appearance of the gemmule upon the main trunks and branches, slighter variations being noticeable in the size of the cellular corpora. Compared with the first case, the dendrites now under examination show diameters averaging not over one-half those found in the first one. They are, as remarked, thinned in transverse diameter, but do not appear to be shortened in their length, both traversing

FIG. 4.

equally long distances in the layers, the longer ones reaching far into the molecular lamina.

Most striking is the difference in the appearance of the gemmules, especially those upon the main branches. Where in the first sections they are closely set together (Fig. 1), stout, the knob-ending fairly large, all colored intensely black by the silver salt, now they only begin to appear on the stems much farther off from the cellular body (Fig. 3), and have much wider intervals between each individual member. Furthermore, those present on the stems are thin, and are not robust looking as in the former example, and the knob termination is of lessened diameter (Fig. 4).

Among the cells, though not in any considerable number, are dendrites coming off from both varieties of pyramidal cells that are irregularly thickened in places, the interval between the tumefaction showing what would appear to be the normal diameter of the branch. Upon the knots are seen sparse numbers of the gemmule, and these present no variations from the staining in the control preparations (Fig. 4). The intermediary cells do not show equal differences with the pyramidal.

The axons and collaterals seem to have no departures from the normal. In both brains they are equally well stained, show no unusual varicosity, or spindle thickenings, and the few endings that could be found showed the usual knob-ending deeply stained. Likewise the neuroglia presented no alteration of moment, the different support and vascular varieties were stained as usual in the several layers of the cortex, but gave no evidence of a disposition toward swelling or the reverse.

Our present investigation does not show accurately the condition of the finer blood-vessels in either case, but the larger ones looked healthy, and nothing approaching aneurysmal dilatations or thrombotic plugs were found.

Chiefly remarkable in the cases is the strong contrast afforded by the psychical cells. We must, perforce, suppose from the general history, that Case No. 2, entered into adult life with an equally good, if not better developed brain-cell than No. 1; but in the second example, owing to the continued dissipation and exposed life, together with the subsequent mental trouble, what a contrast is afforded in their condition at the time of decease. One had been protected for several years in his prison life from vicissitudes, well fed, and restrained from the abuse of stimulants; the other ill-fed, unsheltered, constantly under the influence of toxic drugs exercising a well-marked deteriorative influence on brain-cell nutrition; and the latter, finally, when exposed to microscopic view — after making all possible allowance for post-mortem changes — showed most important retrogressive alterations in the condition of the protoplasm of the cell. That there was nothing of an inflammatory nature in these modifications of the normal nerve-cell is shown by the healthy condition of the neuroglia.

To conclude, we have in the first case a developmental condition of the nerve-cells closely approximating — but of a higher type than that in similar cells from animals whose brains have been fixed in preservative fluids immediately after they have been killed, and all changes of post-mortem alterations removed — a control preparation. In the other we find alterations in a comparatively fresh brain, approximating those found in the brains of animals that have been subjected to the long-continued administration of certain nerve-poisons, among which alcohol may be taken as the most prominent example.

SOME THINGS I WAS NOT TAUGHT IN OBSTETRICS.¹

BY E. S. BOLAND, M.D.

WAS it Horace Greeley who said of a certain self-styled "self-made man" that he relieved his Creator of a very grave responsibility? My instructors cannot be held accountable for my conclusions. Possibly a better title would be "Some Things I did not Learn in Obstetrics."

However this may be, the fact remains that I did not know them upon leaving the Medical School, and they had to be developed from experience, or the application of general principles, though often from current literature and oftener still from the suggestions or hints of others.

¹ Read before the Obstetrical Section of the Suffolk District Medical Society, December 28, 1896

That anything new of value can be found in this paper is doubtful. No doubt many of this audience have reached kindred conclusions; but even so, it may be wise to do what is said to be the best of preaching, namely, to tell people what they know.

The subject is so important and the amount unknown to me so great, that no attempt will be made to do other than glance at a few features which have been more or less before the profession of late. Your discussion will give value to this paper and doubtless each can contribute some important truth to fill the many gaps still left.

It is hard after twenty years of active practice to recall just what definite ideas on obstetrics were fixed in the mind on leaving the Medical School. The professor praised ergot, and had talked about and shown the forceps, but advised against taking the latter with us to a case lest we should be tempted (?) to use them.

At the same time, the gynecologists were doing their best to teach us how to cure vesico-vaginal fistula. It was not till years after that the interdependence of these two lines of teaching dawned upon us, and our respect for the Professor of Obstetrics began to wane.

Those were the days when one justified a masterly inactivity by expressed distrust for all so-called "meddlesome midwifery." Antiseptic surgery was preparing the way for later aseptic triumphs, but the application of its principles to obstetrics was not being generally or enthusiastically tried.

About this time, some English medical journals described and figured an obstetrical bag with its suggested contents, and one can remember how pedantic and fussy such an article seemed. But as years went on, the bag became a fixture, and with its general adoption the practitioner found ready at hand anesthetics, well-adapted instruments, antiseptic materials, needed drugs and dressings. Thus the doctor's time was saved, and what is far more to be rejoiced in, woman was relieved of much of her great primal pain and danger, so that for some years past, less has been heard of "meddlesome midwifery," and fewer women suffer from vesico-vaginal fistula, while fewer die from puerperal fever. The obstetrical bag then, with the training to use its well-selected appliances, represents the evolution of anesthetic, aseptic midwifery of today.

Will you try to overlook seeming egotism while I go a little farther into personal experience, since it is that upon which my conclusions are largely based?

The use of anesthetics habitually in labor was not taught us, even when desired by the patient. If, however, any good reason can be produced against such a practice, which would not be equally applicable to general surgery, one would like to hear it, excepting, of course, in such cases of cardiac, pulmonary or renal diseases as make it inexpedient or unsafe. We believe not only in giving it when asked for, but in urging it upon the suffering patient if timid or reluctant.

Preference is given to chloroform, and whether for simply obtunding the pains or for total anesthesia in obstetric operations we urge that it is safe, easy to give, pleasant to take, rapidly recovered from, and not productive of initial excitement or subsequent vomiting. I believe that as an anesthetic in childbirth, it is practically as safe as ether. Whether this is due to physiological hypertrophy of the heart de-

veloped during pregnancy cannot be told; but except in children under eight, nowhere else is seen such immunity from its bad effects or dangers. Special skill is not required to administer it with such oversight as the operator can give during the early stage of anesthesia.

For administration, a single thickness of flannel stretched over a wire ring four inches in diameter will do, care being taken not to touch the face with this inhaler. An ounce, thus inhaled, will suffice for an average case, as total surgical anesthesia is not usually necessary except for turning or high forceps. That it causes or predisposes to hemorrhage has not been evident in my experience although I have used it during the last ten years in more than a thousand cases. Many times when the patient was getting exhausted from the pains, effort and fear, the rapid pulse has been found to go down several beats a minute, but to increase correspondingly in strength after the administration of chloroform.

As a routine practice, the heart is always examined before giving the chloroform. Under these restrictions, it is an ideal anesthetic during the latter part of the first stage and during all of the second stage of labor. During delivery of the afterbirth or for suturing a perineal tear, it will seldom be necessary. Both ether and chloroform are carried in my bag, but ether is not used once to chloroform hundreds of times. To the sceptical, therefore, let me urge a few impartial trials. Justly proud of her great discovery of that great general anesthetic, *ether*, Boston has not been fair to chloroform.

We were not told to do digital dilatation in tedious but otherwise normal labors where the membranes had ruptured prematurely. With the fingers sterilized this is safe and more sure than are drugs. The use of morphine subcutaneously will make it more bearable, though if the pains are severe, chloroform will be best given, just short of producing unconsciousness. The manipulation also distends the entire genital passage.

Another important thing not taught was, that when such measures have been necessary, or forceps have been resorted to, the routine use of the interuterine douche ought never to be omitted, using bi-chloride 1 to 1,000, and for this purpose the fountain syringe (which must be in the indispensable bag) and the ordinary glass irrigator. These latter have the advantage of metal in that they are transparent. The small size will be found to be very convenient in irrigating after incomplete abortions. No doubt sterilizing will make a blood-clot lodged in a metal irrigator innocuous, but it is not pleasant to contemplate the possibility of it.

The necessity of emptying the vagina and uterus of clots before making the final toilet of the patient was not sufficiently emphasized. This important measure ought to precede the douching.

Again, the value of the prompt suturing of perineal and other vulvar tears at the completion of labor was not enjoined. It would seem, at this date, unnecessary to urge the necessity of this operation did we not know that some practitioners still treat such by denying their existence. In my experience they occur as often in natural as in artificial deliveries, though, of course, they may be more extensive in the latter, especially after instrumental delivery of non-rotating occiputo-posterior head. For some years I have car-

ried the head mirror of the laryngoscope to facilitate the application of the high vaginal sutures in extensive tears. An assistant to hold the lamp is all the help that is needed. Sterilized silk sutures seem best for this purpose. For twenty-four hours after this operation catheterization is advisable, sterilizing the catheter and cleansing the vestibule first.

It is not the fault of our teachers that bi-chloride of mercury was not put in our hands instead of the bulky, benumbing and uncertain carbolic acid. It is indeed a boon, yet we meet some who have not yet appreciated their relative values. The tablets furnished for this night and morning perineal toilet ought to be strongly colored and strict rules given for their exclusively external use.

I am sure that the majority of the profession will agree with me that we are using the forceps much oftener than was thought best twenty years ago. Personally I use them much earlier in all cases seeming to need them than formerly, and with far better results both to mother and child.

It took some time to learn that a severe and protracted labor paved the way for sepsis and hemorrhage, or both, and that almost every instrumental case did well if done early. This fact has permeated the popular mind, too; and now the proposition to use forceps arouses no such dismay and objection as it once did.

I believe axis traction is secured with ordinary forceps by using one hand on the joint as a fulcrum and while less convenient the result is thus obtained. The short forceps have been found of very great convenience; and though both short and long are always carried, the former are much oftener used.

Dismayed by a few unfortunate results in uremic cases, it now seemed best to drop the expectant plan and terminate pregnancy if severe symptoms develop before the seventh month. To delay may cost the patient her reason or eyesight, if not life itself, without giving much chance for a live baby either. After seven months, if within easy reach, and the symptoms are not too urgent, we may temporize. The same line of practice seems best in the case of hydramnios. Very bad results to the mother have been seen from non-interference, with little accruing benefit to the baby.

Little was formerly taught about the mental phases of eclampsia other than the seizure alone. These may be preceded by a period of variable length, of automatic conduct, the patient keeping up and about but in a dazed and uncertain manner. This period will be a blank to her afterward so far as any recollection of it is concerned. If one does not know how to interpret these symptoms, he is liable to be taken unawares by a terrible attack of convulsions or coma which will open his eyes to the real state of affairs with her.

Some women in labor who are not suffering from renal troubles at all, will have what are practically attacks of transient mania during the first and second stages of labor. Morphine hypodermically and chloroform anesthesia will generally give relief, as the cause is pain and dismay.

In the treatment of incomplete abortion it is evident that we have not found it best to keep to the teachings of two decades ago. In some way the impression prevailed that prior to the tenth week there was no placenta, and so when confronted by a case at eight or

nine weeks, giving the history of a ruptured sac with the escape of an embryo, we were inclined to lull ourselves into the fond belief that the worst was over. Soon hemorrhage, pain, and possibly septic absorption with escape of membrane and placental *débris*, made it clear that a slight degree of dilatation might give egress to a small embryo and still be too small to allow the escape of the actually larger mass of secundines even if the latter were detached from the uterine wall. That the placenta may not exist as an actively vascular go between prior to the third month I cannot discuss, but as a matter of fact I *do* find a mass of material very like immature placental tissue after seven or eight weeks. It is the retention of *this* mass with the associated hemorrhage and probability of septic infection and absorption which renders this condition one of insidious and concealed danger. These are often the cases where for moral reasons the fact of an abortion is suppressed until it often becomes its own Nemesis.

Sometimes a frank statement makes the diagnosis easy, but oftener we have to draw our own conclusions from reluctant half-true answers. If we fail to make an examination, valuable time will be lost and the doctor will lose any reputation for acumen which he may have as well. On examination the cervix will usually be found but slightly dilated, but more dilatable than usual. Firm supra-pubic pressure on the fundus and steady gradual insertion of one finger, will find a capacious cavity and touch the mass of membranes, placental tissue or whatever is retained.

The discharge will sometimes have the odor of moist decomposition, but too great reliance cannot be placed on this evidence, as some very septic cases will not give much odor and *vice versa*. The temperature will be up from 102° to 106°, pulse fast and weak from preceding hemorrhage, and an account of chills, sweating, etc., will be obtained.

Occasionally one of these cases will be found presenting an enlarged cervix and an everted os covered with a cauliflower-like granulation. This condition when associated with hemorrhage and fetor may throw one off his guard. Once, after having practised long enough to know better, I sent such a case to Carney Hospital as a case of cancer of the cervix. Luckily for both patient and myself, she fell into the hands of Dr. Swift who relieved her of a retained and fetid placenta.

Since then I have seen another such case, but was forearmed by my previous experience.

The history of an abortion ought to clear up the diagnosis. Whatever question may exist about the treatment of a recent non-criminal abortion, in the case of those with high temperature, chills, fetor, etc., it must be admitted that the only safe course is to empty the womb, and stop further septic irritation and absorption by dilating the cervix, eructing the living and douching with bi-chloride, 1 to 1,000. The dilatation generally secures subsequent drainage so that I have not found the insertion of a gauze drain necessary. No class of cases has given me more satisfaction in the face of unpromising conditions than these.

Too little stress was laid on the value of correct nursing twenty years ago. Among many of our patients this indifference is still surprising. When I found a nurse telling my patient that her hair must not be combed for thirteen days, after delivery; another that she need not fear taking cold from lying in

her own urine; and half the other nurses using mother's milk in the baby's eyes, — I realized that in justice to the patients it was necessary to train some needy, intelligent women for service, and give them the preference over the officious, untidy and unreliable make-shifts whom one would otherwise have to endure. By so doing the patient is better cared for, the nurse is changed from a drudge to a pupil, and the doctor is sure of a nurse who will be loyal to him, an important matter to a young practitioner.

Right here, let me say that if the doctor's lot is cast among those too poor or to indifferent to employ reliable nurses, he must at whatever sacrifices of time or dignity, take off his coat, roll up his sleeves and attend to the indispensable details of nursing himself. Better a half-hour spent in making an unfortunate woman safe and comfortable than to wake at night and reflect on the danger and uncertain outcome of a case which might have been rendered safe.

In the treatment of puerperal fever, little was formerly advised by way of direct treatment to the utero-vaginal cavities. Curetting or inter-uterine injections were regarded as unsafe or too troublesome to give; but medicine and outside applications were unstinted. It was taught twenty years ago that two ounces of alcohol was as much as the system could assimilate to advantage in twenty-four hours. Of late, however, I have seen a septic case (puerperal fever) take ten times as much as that, with good results.

We were warned in school that if puerperal fever occurred in our practice we must give up all new cases for a period. Acting upon this theory I once lost twenty days' work. Lately, however, while caring for a very severe case of puerperal fever in which I had to make applications, give douches and perform other services involving handling the patient, seven other cases of obstetrics were attended, three of which were instrumental, and though forced to do considerable of the nurse's work in these, too, no case showed infection. Sterilizing all the instruments by boiling, disinfecting the hands and bared arms, are precautions which leave little to be feared from contagion.

For the vomiting of pregnancy, our resources were formerly limited to oxalate of cerium, etc. Later experience has taught me to place more reliance upon painting the cervix with a ten-per-cent. solution of argentic nitras, or slight dilation of the os-externa in cases of such severity as call for any treatment.

The benefit to be derived from position and support by well-applied compresses and bandages in suppuration of the breasts were not taught; those were the days of poultices.

What instruction we had in extra-uterine pregnancy was not encouraging either as to diagnosis or treatment. Within the last decade so much advance has been made that we now know it to be far from uncommon, and while startling in the event of rupture it is easily recognized and very hopeful of recovery, if treated promptly by laparotomy.

I regret to say that I have not as yet mastered examination of fetal position by external palpation, nor incised laterally for rigid outlet, nor attempted the recently suggested primary operation for cervical tear, that is, suturing before leaving the chamber.

No doubt the near future will bring many innovations and improvements in our practice. Some have characterized as officious interference these measures that have proved useful to us. Parturition, they say,

is a natural process which, they argue, can be left to nature. They forget that women at present are not in a state of nature. Engleman says that Indian women have Indian babies very easily, but have hard labors when they bear half-breeds on account of the relatively larger heads of the half-white offspring.

Possibly the "new woman," with the advantage of better living, dress, athletic training and general education may need physicians less; but for the present we have to take cases as we find them; and though it is no new or easy field, opportunity is given to save lives and reduce pain.

It requires some temerity to come to this hall and voice platitudes, much more to claim merit for procedures which do not have the sanction of the experts. If it were not known that within a radius of two miles from where we stand, practitioners are waiting for the extrusion of putrid placenta, and ascribing the associated rigors to cold, that scape-goat of the conservative doctor, or treating perineal tears by not looking for them, a dignified silence would best become one.

Between the experts, who can wave aside as "trite" the problems that daily confront us, and the medical moss-backs who will not learn, there is still the bulk of the profession, who need the opportunity to meet and exchange the small coin of personal experience as well as to draw on those whose greater opportunities and broader views enable them to give us the latest and best teaching. To this middle class then, I hope to appeal in this paper, being wholly willing, however, to abandon my way of doing when I can learn of a better.

We can all read at home; but the placid page cannot give us the mental etching which comes from the face to face discussion.

Clinical Department.

A FATAL CASE OF POISONING BY RED OXIDE OF MERCURY: NECROPSY.

BY LOUIS T. MITCHELL, M.D., CHICAGO.

THE following case seems worthy of record on account of the infrequency of deaths from this cause.

John T., aged forty-seven, a machinist, and a native of Sweden, was admitted to the Cook County Hospital on July 9th at 9.10 A. M. He gave a history of having been sick three days with vomiting and diarrhea. Absolutely denied eating or drinking anything that could give rise to his symptoms, and also denied having taken any poison.

On admission complained only of severe pain in abdomen, and especially on the right side. The patient made frequent attempts at vomiting, but ejected nothing save a little clear or greenish fluid occasionally. According to his statement he had considerable diarrhea before coming to the hospital, but he only had one passage during his stay in the institution, which was serous and colored reddish.

Three hours after admission the temperature was 100.2°, respiration, 26, pulse 108; four hours later, 97.6°, 26, and 104 respectively. The patient gradually grew weaker, and died at 7.45 P. M. on the same day. Just before death he acknowledged having taken an unknown quantity of "red precipitate."

Necropsy, fourteen hours post-mortem. Rigor mortis well marked. Pupils unequal, right larger.

No marks in mouth. Base of tongue and mucous membrane of larynx of a deep purplish hue. Pharynx and esophagus normal. Stomach about one-quarter distended with food, colored grayish pink; small lumps of the mineral visible here and there. The stomach walls were coated with a layer one-quarter of an inch thick of pultaceous matter. On washing this off, the mucous membrane appeared pale; it was much softened, and could be readily scraped off by the finger-nail. The duodenal mucous membrane was also softened and the contents here showed much larger lumps of the mineral. No trace of it was found beyond here. The lower part of the small intestine contained considerable fluid similar to "rice-water." The other organs were healthy.

Upon searching the room of deceased a pint whiskey flask was discovered, containing a small quantity of alcohol, with a precipitate of the mineral. It could not be ascertained how much had been taken, nor how long before admission it had been taken.

GUIACOL IN PUERPERAL ECLAMPSIA.

BY J. F. R. APPLEBY, A.M., M.D., WASHINGTON, D.C.

RECENTLY a number of articles on puerperal eclampsia have appeared in various medical journals. In none have I noted a wide departure, in treating this disease, from methods which have been in use for many years.

On the one hand, such remedies as lessen blood-pressure in the cerebral vessels—as blood-letting, chloral hydrate, bromide of potassium, and veratrum viride—have their advocates; while, on the other hand, those which control nervous irritability, such as opiates and anesthetics, are held in high repute by many. All have been found useful, and may become valuable in peculiar contingencies.

It is my desire to call attention to another remedy of which I have seen no mention in connection with this disease, and which, in a limited number of cases has in my hands, proven so satisfactory, that I am assured it will find a leading place among other reliable remedies in this perilous disorder.

When guaiacol is poured upon the abdomen it is rapidly absorbed. Its physiological effect is to cause rapid and marked lessening of arterial blood-pressure, lowering of temperature and free diaphoresis.

These physiological effects first led me to use it in a case of nephritis attended with slight convulsions and a full, hard pulse. This patient was an adult male. Twenty-five drops were poured upon the abdomen, and rubbed in with the tips of the fingers. Relief was certainly marked.

Next I used guaiacol in two cases of puerperal eclampsia, with surprising and happy results. They were primiparas. In the first, labor was progressing favorably; dilatation had been accomplished and the occiput had begun to descend, when convulsions came on, becoming more profound with each recurring seizure. As soon as practicable chloroform was administered and the child, a large male, was delivered with the forceps. On the effect of the anesthetic wearing off, the convulsions returned, whereupon I poured forty or fifty drops of guaiacol (the case seemed too urgent to take time to count the drops) upon the abdomen and gently rubbed them in as in the preceding case.

In a few minutes the pulse became soft, free diaphoresis set in, and the convulsions died away.

The second patient had been delivered by a midwife. Both baby and placenta had come away, when convulsions set in. On arriving at the bedside, I found that the patient was enormously swollen over the whole body, and the pulse was full, hard and tumultuous. The convulsions were almost continuous. They were as powerful if not more powerful than any I have seen in a practice extending over nearly thirty years. It looked like a hopeless case. As with the other patients, I used forty or fifty drops of guaiacol and gave a hypodermic injection of one-fourth of a grain of sulphate of morphia. In less than an hour the patient was sleeping quietly, and no more convulsions followed.

Both of the above cases had albuminuria and were much swollen, which symptoms demanded treatment for a few days. Both made good recoveries, and are now enjoying ordinary health.

For guaiacol there may be claimed certainty of action, speedy relief of urgent symptoms and ease of application which renders it perhaps more desirable and less objectionable than any one of the remedies heretofore used in eclampsia.

In neither case did I find it necessary to make a second application, but would certainly have done so had it been necessary.

Medical Progress.

REPORT ON DERMATOLOGY.

BY JOHN T. BOWEN, M.D., BOSTON.

SARCOMATOSIS WITH PURPURA HEMORRHAGICA.¹

MARTIN and Hamilton, of Montreal, have studied two interesting cases of sarcomatosis associated with so-called purpura hemorrhagica. Fagge, who has reported six instances of this association, advances three possible explanations. First, that a minute development of sarcomatous tissue with vessels made up of embryonic cells, takes place at each hemorrhagic spot; second, that an embolus in the capillary vessels is formed by a metastasis of the sarcoma cells; third, that the cachexia of sarcomatosis may sufficiently account for the purpura.

The first case reported by Martin and Hamilton is that of a woman of thirty-five, who was admitted to the hospital, affected with bleeding from the gums, anorexia, emaciation and numerous areas of subcutaneous hemorrhage. There was vomiting of blood and rapid failure until death in ten days. The cutaneous hemorrhagic areas were in some instances firm, distinctly nodular on deep pressure, and painful. At the autopsy there was found a sarcomatous infiltration of the cervix uteri, ovaries, stomach, spleen, kidneys, adrenals, liver and skin. The growth was shown to have spread by means of the lymphatics, especially those about the blood-vessels, and by an infiltration of the walls of the vessels. The microscopical examination of the skin, showed circumscribed nodules of small round cells, with a great infiltration of the adipose tissue and of the coats of the arteries and the perivascular tissue. No emboli were found.

¹ Martin and Hamilton: *Journal of Experimental Medicine*, November, 1896.

Cultures from the internal organs and from the skin remained sterile.

The second case was that of a woman of twenty-eight who entered the hospital with a history of spitting blood and of the presence of bluish spots on the limbs and body. There was also some hematemesis and a history of gastric disturbance and vomiting during the last five years. On admission she was intensely pale, and was bleeding from the gums and other mucous membranes. The skin lesions consisted of numerous subcutaneous hemorrhages, sharply bounded, slightly elevated, varying in size from a five- to ten-cent piece, and circular or crescentic in form. There were other large subcutaneous hemorrhages that were not raised, which were situated mainly in the folds of the buttocks and the inner surface of the thigh. Before the patient's death, which occurred soon after the febrile manifestations, some of the elevated spots disappeared, others remained stationary. The autopsy showed primary sarcoma of the pelvis which had to some extent followed the course of the lymphatic vessels. The hemorrhagic nodules of the skin revealed the hemorrhage deeply seated in the subcutaneous tissue, and the vessels in the vicinity plugged with spindle cells.

The writers conclude that the purpura in these two cases may be explained by the involvement of the vascular system by the sarcomatous elements. In the first case the perivascular lymphatics were extensively affected, from which point the sarcoma cells invaded the walls of the blood-vessels, forcing their way between the intima and the adventitia. In the second case emboli of sarcoma cells were found in the lumina of the blood-vessels, and at these points hemorrhages were always found. Hence the conclusion that we are here dealing with an embolic purpura. Yet it is not possible to explain all the hemorrhages in this way, as in some places there were extensive hemorrhages with no vascular invasions, and the writers are forced to seek for other factors, one of which is the general condition of the patient, and an altered condition of vessel walls. In the second case the raised nodules cannot be looked upon as sarcomatous metastases as there was no evidence of new growth. They regard it as possible that the ring-like spots are related to the embolic process or to a direct invasion of the cutaneous vessels.

X-RAY DERMATITIS.

Fuchs² relates a case where, after exposure of the left hand to the Röntgen rays for about an hour, intense pain was experienced, especially in the finger-joints, which later became unendurable, so that the test had to be abandoned. The skin was colored a dark brown, especially in the places directly opposite the cathode; the hand was greatly swollen and the skin, especially about the joints of the first and second phalanges, raised in thick folds, with a bluish tint. Close inspection showed that the entire territory exposed to the rays was covered with fine cracks, and the whole produced very much the appearance of a frozen member. At the end of a quarter of an hour, bullæ appeared in different places, some of them of large size. In this case the exposure was certainly long, and the number of rays large.

Drury³ reports the case of a man of thirty-five who

was exposed to the rays for an hour, in order to determine if possible the presence or absence of a renal calculus. He experienced some nausea three hours afterward, but no cutaneous phenomena; and six days later he was exposed again, this time for an hour and a half. Immediately afterward he experienced nausea and weakness, and on the following evening the abdomen at the point that had been exposed to the rays was somewhat reddened as if sunburnt. Later, vesicles and large bullæ developed and were ruptured. There was no pain or itching. The lesions were not seen by Dr. Drury until eighteen days after the second exposure. At that time the patch had all the appearances of an acute eczema, with profuse discharge, and exfoliated epidermis. It was sharply bounded, and measured $7\frac{1}{2}$ by $8\frac{1}{4}$ inches. In about ten days the exudation began to lessen and the epithelium to creep in from the edges. Attempts were made at skin grafting; but two months later there still remained an irregular patch 3 by $3\frac{1}{2}$ inches just above the umbilicus. After the patch began to heal it became very painful and was very sensitive to various applications. Cauterization with nitrate of silver failed to produce granulations, and the wound was covered with a thick, false membrane, which was later on curetted and the actual cautery applied. Sixteen weeks after the exposure an ulcer still remained, covered with a thick, leathery, insensitive false membrane. It was thought that the patient's general condition had much influence on the course of the lesion, as he had a severe renal attack intercurrently, and was in a condition of much mental worry and anxiety. This, together with the pain suffered, Drury believes is answerable for the non-healing of the ulcer, rather than any peculiarity in the process itself.

Dr. King, of Toronto, reports in the *Canadian Practitioner* a case that is reviewed in the *British Journal of Dermatology* for February, 1897; from which we quote. The patient, experimenting with the x-rays, was exposed to them for two hours daily on the average through May, and for six hours daily during June and July. The right side was nearest the tube and coil, and about the middle of June the right hand became swollen and blistered on its dorsal aspect. There was considerable pain. He continued to use the apparatus without further symptoms. Upon ceasing to use the apparatus the hand became perfectly well. In the last week of August he began to use the rays again for seven to eight hours daily, this time with his left side nearest the instrument. After six weeks his lips and left cheek became swollen and tender to the touch, and soon after the left hand became tender, swollen and painful, bullæ quickly appearing. Later, when seen, the skin of the hands was congested, unusually smooth, and the left hand was almost entirely destitute of hair; on the right this feature was not so marked. All the nails of both hands were affected and in process of exfoliation. On the left side of the face there was an entire absence of hair about the temple and for some distance behind the ear, although in these places there had been no visible inflammation of the skin. The moustache and the whiskers on the left side were almost gone and the skin at these points was very smooth. The eyebrows on each side were almost lacking. There was much congestion of the conjunctiva, and the patient thought that his sight was not so good as before.

THE ETIOLOGY OF ACNE.⁴

Lomry has made some interesting investigations of the bacteriology of acne and comedo. As the acne pustule is preceded by the comedo, the work is divided into two parts: (a) a bacteriological study of the inflamed comedo, (b) a bacteriological study of the non-inflamed comedo.

With regard to the inflamed comedo or acne pustule, several theories have been advanced. Barthélemy ascribed it to the action of the staphylococcus pyogenes albus or aureus, Boeck to that of a small micrococcus, while Unna considers it due to a small bacillus which he finds present. Lomry's investigation of the acne pustule in cases of well-declared acne, showed that the staphylococcus pyogenes albus was the only organism constantly present, and that its virulence was weak. By continuous passage of this organism through the animal body, however, it becomes as virulent as the yellow staphylococcus and gradually changes its color until it is indistinguishable from the staphylococcus aureus. It acquires also the property of liquefying gelatine. This micro-organism he considers the cause of the suppuration in the acne pustule.

In the comedo a micrococcus was found, that in its form, white color, feeble tendency to liquefy gelatine and its slight degree of virulence corresponded accurately to that found in the acne pustule. This coccus also assumed a yellow color by passing through the animal body and increased in virulence. The writer concludes that it is the same in both pustule and comedo, and represents the staphylococcus pyogenes albus.

Investigations were then made of the comedones and acne pustules that occasionally occur on the faces of people whose skin is habitually clear. Just as many micro-organisms were found in this class of cases as in people with pronounced acne, and the organisms found were the same.

The small bacillus described by Unna, and regarded by him as of etiological importance, was found both in acne patients and in those free from the affection. A great similarity was found to exist between this bacillus and the bacterium coli commune. After several passages through the animal body the few points of dissimilarity vanished, so that Lomry finally comes to the conclusion that Unna's special bacillus is merely a less virulent variety of the bacterium coli commune.

The conclusion is reached from these investigations that the cause of acne does not lie in the action of a microbe alone, but that we must assume that a modification of the secretion of the sebaceous glands exists, — that the soil must be previously prepared. Contrary to Unna's belief, there is no specific acne-organism. Unna's bacillus of acne is a less virulent variety of the bacterium coli commune, and is not constant, while the staphylococcus albus is found in many other skin affections.

SO-CALLED MERCURIAL EXANTHEM.⁵

Neisser does not question the occurrence of a true mercurial drug-exanthem. He recognizes not only the local follicular-pustular form, the erythemata and eczemas, but also a disseminated scarlatiniform eruption, which is often universal and accompanied by fever and severe general symptoms, and may result in

an exfoliative dermatitis prolonged for weeks. The follicular eruption is especially apt to occur in regions where the hair is thick, and the sweat secretion abundant. This form of mercurial dermatitis apparently occurs only from direct local application of the drug.

The diffuse forms of erythema, eczema and exfoliative dermatitis follow internal and subcutaneous application of the drug, as well as external. Rosenthal has remarked that the portions of the mucous membranes that can be seen are affected in the same way as the skin. The fact that oftentimes very small doses have been followed by the most severe exanthems, proves that idiosyncrasy plays a prominent part in these manifestations.

At Neisser's clinic, two-thirds of all the cases of syphilis have been treated of late by the subcutaneous injection of insoluble mercurial salts. In no instance has a general mercurial exanthem followed their use. Neisser thinks that the subcutaneous injection of insoluble salts has decreased the number of cases of mercurial exanthem, stomatitis and salivation. He has met with no accidents in the thirteen years during which he has practised these injections. He has also never seen a true diffuse mercurial exanthem follow the inunction cure, although follicular inflammations have frequently occurred. No bath is taken until the end of the cure, about the sixth day, and the same woollen garment is worn day and night. Neisser believes that the essential action of the inunction cure consists in the absorption of volatilized mercury, and considers therefore the best method of inunction one that favors this volatilization most. He thinks that many cases of dermatitis are laid at the door of mercurials that are really due to impure constituents or badly prepared mercurial ointments. An analysis of a number of specimens of mercurial ointment bought at various drug shops in Breslau, showed that the irritating effect might be due (1) to the employment of volatile substances, especially turpentine, in the extinction of the mercury; (2) to the use of remnants of other ointments, which were not rancid, but contained irritating substances; (3) to the use of fats with a high acidity. Many of the eczemas seen in cases where mercury is employed correspond completely with the so-called turpentine exanthems.

A large proportion of the mercurial exanthems are caused by the application of a large amount of mercurial ointment for the extinction of pediculi pubis. These are often prescribed by the apothecary without a physician's prescription, and in many instances at least, the irritating effect is due to the presence of impurities.

THE ACTION OF SALICYLIC ACID ON THE SOUND SKIN.⁶

That salicylic acid has a keratolytic action on the skin has long been known, and its use of late years in dermatology has been continually extending. Menahem Hodara undertook to study its action histologically, in order to obtain a better understanding of its effects as observed clinically. Unna was the first to point out its virtues as a sure means of removing the normal or pathologically thickened horny layer in the form of a whitish membrane. The action of the acid is confined to the horny layer, and an oozing surface is never seen.

The experiments were performed by applying sali-

⁴ Dermatologische Zeitschrift, August, 1896.

⁵ Proceedings of the Fifth German Dermatological Congress.

⁶ Monatsheft. f. prakt. Derm., August 1, 1896.

cylic acid in varying strengths, and in the form of both ointments and collodion, to the skin of man, and of rabbits, and examining histologically the parts to which the application had been made. It was found that when applied to the human skin for two to three days in the form of plaster, salicylic acid produced a swelling of the horny layer, which was broken up into lamellæ. These exfoliated lamellæ were thicker, when the percentage of salicylic acid used was greater. There was a moderate intercellular edema of the prickle and granular layers.

When the salicylic plaster was allowed to remain for from eight to ten days, the prickle layer was found necrotic to various depths. This result was not even, however, as there was more necrosis at some spots than at others. After this skin has become necrotic the process of casting off and of new formation begins at once. A vigorous proliferation begins in the deeper layers and in the adjacent epithelium, and a new prickle-cell layer appears beneath the necrotic mass. A new granular and horny layer is also produced.

Salicylic acid (30 per cent.) in collodion acts more energetically on man. As early as the third day after its application there is found, together with the changes in the horny layer, a great swelling of the prickle layer, caused by a pronounced inter- and intra-cellular edema. There is also a necrosis of the prickle layer in places. This portion of the prickle layer is finally thrown off from the young epidermis, which has been formed beneath it.

Salicylic acid in man causes no emigration of polynuclear leucocytes, and they play no part in the throwing off of the necrotic tissue. Its action is far more that of causing in the corium a slight inflammation, which is shown by a dilatation of the vessels and by a proliferation of the perithelial and intervascular connective-tissue cells. In the rabbit a concentrated salicylic acid plaster causes a complete death of the whole epidermis with suppuration.

Briefly, therefore, salicylic acid in small amount on the healthy skin causes an exfoliation of the horny layer; when employed in larger quantity and for a longer time, it produces a scaling which is derived partly from the horny layer, partly from the prickle-layer which has become necrotic in places.

EOSINOPHILES IN DERMATITIS HERPETIFORMIS.

In 1895, Leredde and Perrin⁷ published the results of their study of the pathological anatomy of Duhring's disease, the material in the first instance being taken from a woman who suffered from attacks of erythematous and bullous dermatitis during successive pregnancies, the type of disease known as herpes gestationis. The examination of recent papules surmounted by vesicles, showed the corium to be the seat of an abundant cell infiltration, especially about the vessels, consisting of large oval cells with distinct nuclei, lymphocytes, and smaller cells with nuclei surrounded by granulations which stain deeply with eosine and other acid aniline coloring agents. These latter cells are found almost exclusively at a distance from the vessels and correspond to those described by Ehrlich as occurring in the blood, under the name of eosinophiles. These cells are seldom found in the skin, although occasionally met with in inflammations in the vicinity of the vessels. In this case their num-

bers and their remoteness from the vessels are striking features. As for the epidermis the rete is moderately hypertrophied and at about its centre are seen vesicles, which have evidently been formed between the epithelial cells and not in them. This *intercellular* formation of vesicles in Duhring's disease has been also described by Unna. The contents of the vesicles consist of cells grouped together, almost all of which contain eosinophilic granules. The liquid from the vesicles, examined according to Ehrlich's method for the blood, gave in a total of 227 white globules, 214 with eosinophilic granulations.

Three other cases of dermatitis herpetiformis, not connected with pregnancy, were examined, with the result that eosinophilic cells were found in great abundance, both in the cutaneous lesions and in the blood. They were also present as migratory cells in the epidermis. An examination of the fluid from other vesicular and bullous cutaneous diseases revealed no increase in the number of these cells. The conclusion is therefore reached that an alteration of the blood is the essential element of Duhring's disease. The theory is advanced that the kidneys fail to excrete a toxic substance, which is taken up by the white blood corpuscles and eliminated by the skin. In a few cases of pure pemphigus no increase in the eosinophiles was found, which the writers regard as an additional reason for the separation of this disease from dermatitis herpetiformis.

Hallopeau and Laflitte⁸ report two cases of dermatitis herpetiformis where numerous eosinophiles were found both in the blood and in the contents of the vesicles, while none were found in a case of pemphigus foliaceus.

Darier⁹ was also able to confirm the observations of Leredde and Perrin. He found the lesions considered by them as characteristic, namely, an edema of the papillary portion of the corium, resulting in vesiculation, and a notable increase of eosinophilic cells. The same increase in these cells was found in the fluid from vesicles and in the blood. He thinks that further researches are necessary before the exact diagnostic value of the presence of eosinophilic cells can be determined. His own investigations have not shown an appreciable increase of the eosinophiles in vesicles of eczema and of different artificial dermatitides. On the other hand, in a case of leprosy with bullous lesions, a great increase was found in the eosinophiles of the blood, none however, in the contents of the bullæ.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. THE SECTION FOR OBSTETRICS AND DISEASES OF WOMEN.

C. H. HARE, M.D., SECRETARY.

REGULAR Meeting, Wednesday, December 23, 1896, DR. F. W. JOHNSON in the chair.

DR. E. S. BOLAND read a paper on

SOME THINGS I WAS NOT TAUGHT IN OBSTETRICS.¹

DR. TWOMBLY: Experience is a great teacher, and since leaving the school I have learned many of the

¹ See page 254 of the Journal.

⁷ Annales de Derm. et de Syph., 1895, p. 1442.

⁹ Loc. cit., p. 842.

⁷ Annales de Derm. et de Syph., 1895, p. 281.

things which Dr. Boland has mentioned. It is well to call them to mind and discuss them. The paper certainly is very desirable. One of his principal points was the use of chloroform instead of ether. I do not know that the majority of our obstetricians in Boston use chloroform so extensively as he does—not that there is any objection, because we know it is practically harmless in labor, that it can be used and freely used without danger, that the deaths under chloroform during labor have been practically nothing, and, that if there has been a death, it has generally been due to another cause. The majority of us use ether, simply because ether is “the thing” in almost all operations here in Boston. Ether works just as well and gives us practically no anxiety at all. Chloroform ought not to trouble us in such cases, but still we have a confidence in ether as we are using it all the time—at least I do—that we have not in chloroform. I should feel anxious to see that the little disc was held away from the patient, and that they did not give her too much while the pains were going on; with ether I can attend to my own part of the procedure and know that all is well. Ether is said to retard labor. I have seen that occasionally, but I do not think it necessarily is a disadvantage. I have not found that ether causes vomiting where even complete insensibility is produced for any obstetrical operation. Perhaps I should be convinced by Dr. Boland’s large experience that I could use chloroform more freely. Certainly chloroform is all right, and yet for certain reasons—because we are born and bred up to it—we use ether instead of chloroform in the majority of these cases.

As regards the early stage of the formation of the placenta, I too have noticed that, since I came out of the school. Dr. Boland has mentioned that we were taught that the placenta was not formed until the end of the third month. Certainly we find that it seems to be formed very much earlier in cases of abortion; and in almost every case at the sixth week or at two months I find it necessary to dilate and curette with the finger or with an instrument to get out the remaining *débris*. In one case I remember curetting until I could feel the uterine tissue, and I thought everything had come away, but washing out brought away a great deal more. The next day a great mass of placental tissue was expelled, and there had been some hemorrhage and pains in the night. I found my curette had gone round and round this mass while curetting the part of the placenta that adhered to the uterine wall, and it was free in the interior of the uterus and acted as a foreign body until the uterus expelled it. I think we do not always dilate enough to get this free mass out, neither does it always come through the opening when we wash out with a large tube. Here comes in the value of an aseptic finger which ought to be used to prevent such mistakes.

As regards the use of forceps we are all coming to use them very much earlier than we used to, and it certainly is a wise procedure where the labor is prolonged and the patient becoming exhausted. It prevents bruising and wounding of the soft parts by long-continuous pressure, and prevents sepsis through a torn or injured vagina; but I think each case should be treated on its own merits, and each physician must decide for himself. It is better to apply them a little later than to put them on too early in each case.

As regards the intra-uterine douche I know my

friends at the Lying-in may differ; but in my private practice I do not use the douche as often, either before or after labor, and I am coming more and more to palpate the position of the fetus externally, making fewer and fewer vaginal examinations. Leopold, of Dresden, teaches that decidedly, and admits of only one vaginal examination during the whole time. If, however, the hand in the uterus or high forceps are used, I should use the douche afterwards. If the labor has been natural, or low forceps used, and the field aseptic beforehand, I think the douche can be omitted as a general rule in private practice.

DR. GARCEAU: I have only one procedure to relate which, so far as I know, is not to be found in the text-books. I refer to the treatment of certain early miscarriages—those which have been induced by means of the catheter, and in which sepsis has followed the introduction of the instrument. If the sepsis is accompanied by severe general symptoms and the uterus still contains the infected placenta, held there by a rigid os, the placenta necessarily is a menace to the woman’s life. Under these circumstances the saving of a few hours may mean a great deal, for by acting promptly we may prevent serious results. Even if the woman recovers, the invasion of the tubes and ovaries may lead to a chronic inflammation of these appendages which perhaps may necessitate a subsequent celiotomy for their removal. Those who have to do with gynecological work know that a large proportion of cases of salpingo-ovitis have their origin in a badly managed miscarriage, and a common remark in the out-patient clinics is, “I had a miscarriage a few years ago, and I have never been well since then.”

If sepsis has declared itself, the treatment should be in all cases, early removal of the uterine contents. In most cases this is done without difficulty; but there is a certain class of cases in which there may be some difficulty on account of a rigid os. To overcome this the usual method is, introduction of a strip of iodoform gauze in the cervical canal, which is allowed to remain there for a certain length of time, when it is removed and a larger piece put in. This is repeated until sufficient dilatation is secured. Against this procedure is the fact that it consumes valuable time. In the very early months of pregnancy all that is necessary to do is to dilate with a stray dilator and remove the partially formed placenta with a small curette. But when the placenta is formed, as it is in the later months, a small curette will not suffice to remove it with certainty, and a small piece of infected tissue left behind may do all the mischief that the whole placenta might. The safest way in these cases, it seems to me, is to give ether, dilate as much as possible, and if sufficient dilatation is not secured, to incise the cervical canal with a knife on either side, introduce the finger in the uterine cavity and remove the placenta; the caual and incised cervix may then be sutured.

I have treated two cases in this way. In the first the woman was, when I first saw her, evidently septic. She had a temperature of 103°; was much prostrated, and was having chills; there was likewise a foul vaginal discharge. There was no question that she was not then having a miscarriage. On examination I found a rigid os and a large uterus. I gave her ether, incised the os in the manner described, and removed the placenta. There was no fetus, it having been

passed a short time before. She made an uninterrupted recovery, and became pregnant again in six months. In the second case the pregnancy was advanced to four and a half months. She also was septic, and was having chills and high temperature. Here also I incised the os, and removed a macerated fetus and placenta piecemeal. She recovered perfectly.

The great advantage of the finger is that you can assure yourself that nothing of an infectious nature is left behind.

In reply to Dr. Twombly's question I would say that in incising laterally I merely did so because most lacerations of the cervix are lateral, and I endeavored to follow nature in this respect.

DR. CUMSTON: I was very much interested in the reader's paper, especially in the subject of chloroform, because when I was at the Rotunda Hospital I had considerable experience with that there, and saw it used in confinements; in fact, they never use ether. I agree, as far as my observation goes, with the speaker in that chloroform is a harmless anesthetic in every way, and personally I prefer it to ether in labor when surgical narcosis is not necessary. If operative interference is necessary, I think I should resort to the use of ether. But a very admirable way, to my manner of thinking, of giving chloroform during labor to control the pains is what the French call *chloroform à la reine*, which came from the practice of Dr. Simpson with Queen Victoria, who was the first to take the narcotic as she wished to set a good example to English women. You give the patient a handkerchief and a small bottle of chloroform, and every time she feels a pain coming on she will pour a little chloroform onto the handkerchief, then put it to the nose, and as soon as she gets enough the arm will be relaxed and will fall from the nose; consequently there is no danger of an overdose. We used to employ it in that way in the Maternity at Geneva and Dublin, and it worked very well.

The question of infection in early miscarriage or abortion I was very glad to hear the doctor bring up. I have seen in my dispensary practice a few cases in which I am very positive the miscarriage or abortion had taken place at about two months or two and a half months, and still the patient was septicemic. I make a distinction between septicemia and what is called sapremia. I think the cases in which you have a fever going up to perhaps 38.05° C. where chills are not very marked and the patient feels fairly well, are due to the absorption of the microbic toxins in the uterus without systemic infection from the microbe itself. Septicemia is entirely a different affair. I hardly think unless the miscarriage is artificially produced, that you will find a true septicemia unless there has been some meddlesome work done, unless the *accoucheur* has introduced his finger not properly cleansed, or dirty instruments; in that case he will introduce other germs and add fuel to the fire. In this way, perhaps, a true septicemia may result.

To illustrate the sapremic condition following early miscarriage, that is to say, before the end of ten weeks, I would mention a case that occurred in my private practice not long since, which Dr. Garceau had the kindness to help me with. A physician's wife, twenty-three years old, was said to be quite sick, and the doctor asked me to see her. I saw her about five in the afternoon, found a temperature of 101° F., the face a little flushed. Upon questioning, all the history I

was able to elicit was that the patient had skipped one month, and that it was then the time for the second epoch to occur. At the time of the preceding menstruation there had been a little show, simply a serous liquid tinged with blood. This time there was a slight flow of the same nature. Although I examined the napkins I could not detect any abnormal odor. I consequently was a little lost in the diagnosis. Vaginal examination showed the uterus in physiological anteversion, enlarged to the size of a uterus at six weeks, but deviated to the right of the median line and slightly tender. As it was her first pregnancy, I was rather under the impression that it was probably a little attack of grippe, and that there really was no threatened miscarriage. The next day the temperature had gone half a degree higher, the night had been bad, and the flow had slightly increased in amount, although not more than one napkin would have been necessary to use in the twenty-four hours. The napkin of the morning I examined pretty thoroughly, and found, which to me is a very valuable sign of a septic process going on in the uterus, that the centre was clear in color and its borders dark. Not wishing to act too hastily, I asked Dr. Garceau to see the case with me, which he did; and we decided to wait until evening before interfering. We saw the patient at eight o'clock, and as she was no better, according to Dr. Garceau's suggestion I introduced a strip of iodoform gauze into the os to obtain dilatation, and we saw the patient again in an hour and a half. Although dilatation had not gone on to any extent, I proceeded to dilate and curette with the result that a large mass of fungosities was removed, although no trace of a fetus could be found. The patient was put to bed, and the next morning the temperature was almost normal. The temperature remained normal two days, and then suddenly went up to 38° C. I gave an intra-uterine douche of creoline, and from that time on the recovery was uninterrupted. Now the uterus is normal, no tenderness; and I think she has very luckily escaped a good deal of trouble.

Regarding the removal of the retained *débris*, that has happened to me several times. I had a dispensary patient a year ago in a septic condition, bleeding quite profusely, and the discharge had an extremely bad odor. I removed a large mass of placenta with the curette. I thought I had been over the cavity very thoroughly; but a few days later not only was a large piece of the placenta expelled but the fetus along with it. Consequently, my rule has been, since that time, to use a curette that would cover as large a surface as possible; and I see nothing that would answer the purpose better than Dr. Reynold's instrument.

DR. BOLAND: In regard to the intra-uterine douche, I use it only after some intra-uterine operation. I do not repeat it unless the temperature goes up. I do not leave it to the nurse at all. In regard to incomplete abortion, if I see the ovum in the unbroken sac and the embryo not bigger than a bumble-bee, I feel pretty easy.

I never trust the bottle of chloroform to the attendant or nurse, but keep it within reach; and if I have to use forceps I drop on ten or twelve drops at a time. I think in an ordinary case where surgical anesthesia is not desired an ounce will suffice.

I tried to make a distinction between surgical irritation and septicemia. I am not quite familiar with the

term Dr. Cumston used, but in my paper I spoke of septic irritation in the sense of surgical irritation.

In regard to cancer of the cervix, I felt terribly mortified and sore over that case. I had never met it before. The cervix seemed as large as the end of the closed hand; it was soft, and bled on touching; it was coarsely granular, and I was sure I had a case of cancer of the cervix. I could not get a clear history of abortion. I sent her in, and was nonplussed when I found the doctor had taken away the placenta.

DR. C. G. CUMSTON read a paper on

HYDROCELE OF THE CANAL OF NUCK, WITH REPORT OF A CASE.

DR. GARCEAU: I should like to ask whether the reduction which was done two or three times by other physicians was a reduction *en masse* into the abdominal cavity?

DR. CUMSTON: I do not believe they ever reduced it. I think after a while the tumor became inflamed by the truss, and the local irritation caused the secretion of fluid in its interior to continue. I think the doctors were mistaken when they said they reduced it. That they might have flattened it I dare say, but reduction must have been impossible in this case because, when I operated, the inguinal canal was one of the smallest I ever saw. In the true form, reduction into the abdominal cavity never takes place.

DR. JOHNSON: I once met with hydrocele of the canal of Nuck in doing an Alexander operation. It was on the left side, and it was supposed that the woman had a left inguinal hernia, and she also had a retroflexion of the uterus, and I thought I would do an Alexander to correct the retroflexion and cure the hernia; but I found it was a hydrocele of the canal. That is the only case I have seen.

DR. CUMSTON: Could the tumor be reduced before operation?

DR. JOHNSON: I made no attempt to reduce it. She told me she had worn a truss. Under ether you could push it in so that it did not protrude beyond the level of the skin, but you could feel it. I supposed it was a hernia. It was oblong, about the size of a small hen's egg. It was about one and a half inches in length.

Recent Literature.

A System of Surgery. In contributions, by twenty-five English authors. Edited by FREDERICK TREVES, F.R.C.S., Surgeon to, and Lecturer on Surgery at the London Hospital, Examiner in Surgery at the University of Cambridge. Vol. II. In one octavo volume of 1120 pages with two colored plates and 487 illustrations. Philadelphia and New York: Lea Brothers & Co.

The object of this work is to present a concise account of the science of surgery as it exists to-day, and to present pathology, clinical data, and treatment in a form useful not only to a medical student but also to the surgeon in active practice. Operative technique is omitted, this subject having been thoroughly and very satisfactorily treated in Mr. Treves's excellent work on operative surgery ("Manual of Operative Surgery," by Frederick Treves, two vols.).

The contributors to Volume II are men more or less identified with the subjects assigned them; especially Bennett, Pearce Gould, Henry Morris, Ball, and the editor himself. This book is devoted to the surgery of special regions. It describes the affections of the head, mouth, palate, tongue, tonsil, pharynx, esophagus, ear, nose, neck, chest, spine, breast, abdomen, hernia, rectum, kidney, bladder, male and female genital organs, muscles, tendons and deformities.

The articles are more thoroughly written even than those in Volume I. Some are very valuable contributions. The same satisfactory division of articles into specific subjects by heavy, clear type headings appears in this volume as in its predecessor, making rapid reference easy. The illustrations and diagrams are well chosen and effective.

When one considers the extent of the task of condensing into two volumes practically all surgical science, one is struck with the completeness of Mr. Treves's work. An index to both volumes is appended to Volume II. The book, although containing 1120 pages, is not too heavy to be read without inconvenience, and is surprisingly compact. It is a book that one can unhesitatingly recommend to those whose professional work causes them to be interested in surgery.

Fear. By ANGELO MOSSO. Translated from the fifth edition of the Italian by E. LOUGH and F. KILSON. Authorized translation. London, New York and Bombay: Longmans, Green, & Co. 1896.

This is one of the works which the brilliant physiologist of Turin has written more especially for a popular audience, and is a good example of the somewhat peculiar method followed by him in making books of this kind. Nothing comes amiss that can in any way be brought into connection with the subject he is writing about: physiology and psychology, art and literature, the professional and general experiences of the author himself and of others being all called upon to furnish material for the work, which in its final form suffers from considerable diffuseness and lack of sequence, much that is introduced failing to make its structural importance felt. On the other hand, nothing can be said to be without interest, the writer's geniality (in the German as well as in the English sense of the word), freshness and spontaneity (often indeed *naïveté*) quickening everything.

The book contains a brief sketch of the functions of the central nervous system, an account of the influence of emotion on the intra-cranial circulation, and a discussion of the effects of psychical conditions upon the circulation, respiration, and other bodily functions. A large part of the work is given to the discussion of the expression of the emotions, particularly of fear, in which Mosso shows himself to be largely a disciple of Spencer and Darwin. The medical and educational influences of fear are also entered into.

The translation is, on the whole, fair. It is to be regretted that here and there such sentences occur as: "In the middle of the auricle of the rabbit's ear there is an artery, running from the base to the summit, which ramifies and winds in such a manner as to form two veins on the edge of the auricle" (p. 11), and "The turbidness appearing on the whitish leaflet of the germ seems to be regulated from the beginning of the division of labor" (p. 262), where at least "from the beginning" should be replaced by "by the principle."

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MARCH 18, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE REPORT OF THE COMMISSION ON THE
PUBLIC CHARITABLE AND REFORMATORY
INTERESTS AND INSTITUTIONS OF THE
COMMONWEALTH OF MASSACHUSETTS.

THE Commission, consisting of Hon. William F. Wharton, Dr. C. F. Folsom and Prof. Davis R. Dewey, appointed last May by the governor, to investigate the charitable and reformatory interests and institutions of the Commonwealth of Massachusetts, has sent in its report, which is now before the legislature. The report with appendices will be published and ready for distribution at an early date.

The Commission recommend:

First, the creation of a Department for Children, for the care, custody and control of the more than two thousand juvenile offenders, dependent and neglected children and foundlings or destitute infants now under the charge of the State, to be composed of seven unpaid members.

Second, the creation of a State Board of Insanity, to be composed of a chairman and two other members serving without pay except their expenses, and two members to receive each a salary of \$5,000 a year and necessary expenses.

Third, a State Board of Charity, of seven members, of whom the secretary is to receive a salary of \$3,500 and expenses.

Fourth, a simplification of the settlement laws and less difficulty in acquiring settlements.

Fifth, certain changes in the laws to render the Foxboro Hospital (for dipsomaniacs and inebriates) experiment more successful.

Sixth, State control of all the penal and reformatory institutions, and the abolition of the county houses of correction as such, with the following ends in view:

- (1) The abolition of unclassified prisons.
- (2) The initiation and development of reformatory measures for a larger number of prisoners who are susceptible to reform.
- (3) Uniformity in the management of the prisons and the prisoners.
- (4) Uniformity in the terms of sentences and in the granting of permits to be at liberty.

- (5) The better regulation of labor in the prisons.
- (6) The more complete separation of the sexes.
- (7) The abandonment of prisons now quite unfit for their purpose, as, for instance, the House of Correction at South Boston, and wiser provisions for relieving our overcrowded prisons.
- (8) The more intelligent study and treatment of the problem of drunkenness.

Seventh, the abolition of fines as punishments for drunkenness, the placing of occasional drunkenness without other offence against the law outside the list of crimes and misdemeanors, and the subjection of habitual and confirmed inebriety to reformatory treatment.

The Commission also recommends that the Board of Commissioners of Prisons consist of two salaried members and of three members, including the chairman, who receive no pay except for necessary expenses.

The Commission recommends that all insane persons, acute and chronic, who are supported at public expense, be placed under the care, custody and control of the authorities of the Commonwealth, and that the expense of their support be borne entirely by the Commonwealth, taking them entirely out of the hands of the local authorities and from the uncertainties of almshouse treatment. It also advises that the State Board of Insanity should have charge of the boarded-out insane until their number reaches such proportions that a separate department should be created to take charge of the work. The trustees of the several hospitals for the insane are to be allowed to board out any of their patients, subject to the supervision of the State Board of Insanity.

The recommendations as regards the insane chiefly interest the medical profession, and we quote the Commission's general suggestions upon that point in full:

Great weight should be attached to the thorough inspection of all the hospitals and asylums for the insane brought under the supervision of the State Board of Insanity, and in order to insure such inspection we would suggest that the following provisions be incorporated in the law and made mandatory:

- (1) That the Board or any two members of it should visit every hospital and asylum under its supervision at least twice a year.
- (2) That every part of the institution visited should be carefully inspected.
- (3) That every patient should be interviewed, or an opportunity offered to each one to hold an interview.
- (4) That every certificate of commitment entered or filed since the last visitation should be inspected.
- (5) That entries should be made by the visiting Board or the visiting members in a visitor's book of minutes of the condition of the institution at that time, of the patients therein, of the patients under restraint and their number, and any criticisms or observations that the Board of visiting members may have to make, — for instance, as to the occupation, amusement or classification of the patients, as to the cleanliness and sanitary condition of the institution, as to the diet of the patients, and any other matters that they may deem worthy of observation or criticism.

We further recommend:

That all patients in any hospital, asylum or receptacle for the insane shall be allowed, subject to the regulations of the Board, to write freely to the State Board of Insanity, if created, and that the letters so written shall be forwarded unopened by the superintendent or person in charge to the said Board, for such disposition as it shall deem right; and that the said Board shall have the right to send any letters, or other communications that it may deem proper, to such patients.

That whenever any person is received by the superintendent or physician in charge of any insane hospital or asylum, and

there is a question as to the propriety of his or her commitment, the said superintendent or physician shall immediately notify the State Board of Insanity, who shall inquire into the insanity of such patient and into the question of the propriety of the commitment.

That, in taking and transferring patients to and from the institutions for the insane, the nurses of the hospitals and asylums should be employed, as far as practicable, instead of officers of the law.

That a uniform system of keeping accounts in the several State hospitals and asylums be prescribed by the State Board of Insanity, and that the same be universally adopted by those institutions.

That the State Board of Insanity and the boards of trustees of the several hospitals and asylums for the insane, whose responsibilities should not be lessened, meet quarterly for purposes of consultation and harmonious action. Some of the topics to be considered at such meetings might be the apportionment of patients to the several hospitals and asylums, the examination by experts of questions of diet, ventilation, drainage, new construction, improved facilities for treating acute curable cases, occupation for the patients and gymnastics as a means of physical and mental training.

That there be referred to the Board or its officers questions of the sanity of inmates of the penal, reformatory and other institutions who present indications of insanity.

That the use of the word "lunatic" be abandoned, and that the term "insane" or "insane person" be substituted for it wherever it occurs in the names of the several hospitals and in the laws relating to the insane.

The presentation of this admirable report marks an epoch in the history of the charitable and reformatory work of our Commonwealth. The three commissioners were men of eminent intelligence, and unswayed by selfish or political considerations, and they have had the opportunity, and seen fit to utilize it, of looking over the whole ground, and formulating a comprehensive and consistent scheme, whereas the General Court is ordinarily called upon to make one and another single change which the exigencies of the moment seem to demand, so that their reforms are almost necessarily a sort of patch-work.

The task set before them has been accomplished by the commissioners in a masterly way and evidently as the result of deep study and thought, after consultation with every one who wished to be heard on any part of the problem. Their recommendations can hardly fail to be a guide for present and future legislation, for they express the best knowledge of the best men in the community.

With the general aim of carrying out fully the plan which is already somewhat in vogue, they propose to place the different blocks of work—the care of the paupers, of the children, of the insane—under the charge of unpaid boards of trustees, who shall be or become, to a certain extent, experts in their several departments; and to provide for adequate supervision of their work by the appointment of a Board of Charities and a Board of Insanity, who shall not be hampered by administrative duties.

The supervision thus provided for is not a mere contrivance for criticism, but a scheme for the encouragement and stimulation of the individual boards of trustees, with due regard to the general interests of the Commonwealth.

The State Board of Health occupies already a truly judicial position, and its opinions are respected by the

local boards, because its members are recognized as authorities in their branch; and these proposed boards would soon come to occupy the same position as regards scientific charity and insanity. It is probable that any measure asked for by the boards of trustees, and endorsed by these supervising boards, would promptly be granted by the legislature; and so the supervising boards would inevitably have both a stimulating and a restraining influence on the trustees of the individual institutions.

The recommendation that all the penal institutions and the institutions for the insane, should be placed under the charge of the State, so as to bring about a more efficient and more uniform administration of them, would be a step forward of which physicians should eminently approve.

There may be objections to this arrangement, on the part of the county and municipal officers, because it takes away some of their present power and prerogatives, or for other reasons; but in the end they must surely see that it will work to the general good.

Under the present arrangement each of the local boards must study by itself the subject of crime, of pauperism or of insanity on such a small scale that its conclusions are likely to be narrow and its methods inharmonious; whereas the supervising boards would be able to collate the best experience of the world, and to suggest such methods of application as would be suitable for individual cases.

The changes suggested by the commissioners in the Settlement Law, by which settlement is acquired in three years instead of five, may also meet with opposition. But it must be remembered that if paupers are not taken care of by the towns they must be taken care of by the State, so that the taxes come ultimately from the same persons; and also that large sums of money which are now spent in determining settlements will be saved to the tax-payers under the new scheme. These changes in the Settlement Law have, as a matter of fact, been approved by the Association of Relief Officers of the towns.

Among the most valuable of the recommendations of the report is that providing for a special department for all the children now placed out in families throughout this and neighboring States.

There are, it should be said, well-informed persons who doubt whether it would be wise to change the status of those children of the Lyman and Industrial schools not actually in the schools but placed out under their custody, on the ground that the selection of the best places for these children and the return of them to the school when necessary, cannot be conducted by anybody else so well as by the officers and trustees of the schools themselves.

Well informed persons differ with the Commission in other matters, and other plans will be proposed. The sincerity of the opposition of members and officers of the Board of Lunacy and Charity, their zeal and the excellence of much of their work under difficulties entitle them to a respectful consideration.

These reforms seem to us so important that the legislature must in the end adopt them, in all essential respects, and if it does not do so this year, it may delay but it cannot permanently check the tide of progress. Public opinion is now strongly roused; and its force can be counted upon by those public-spirited legislators who are endeavoring to accomplish the adoption of these improvements.

THE REGULATION OF PRIVATE HOSPITALS FOR INFECTIOUS DISEASES.

IN a recent number of the JOURNAL (February 25, 1897) the provisions of a bill introduced in the Massachusetts State Legislature, for the regulation of private hospitals for infectious diseases were published, and since then several hearings have been given at the State House before the Committee on Public Health to the supporters and the opponents of the bill.

Although including all of the various so-called infectious diseases like small-pox, diphtheria, typhus fever, etc., the bill was professedly framed by owners of real-estate in Dorchester who have strenuously opposed the further existence of two private institutions for the care of consumptives in that district on the ground of the great danger in which these hospitals are supposed to place the surrounding community.

During the past year or two we have had some extraordinary examples of the lengths to which the laity will go in their discussions upon matters pertaining to public health. Views even more extreme than those of some of the medical profession themselves are expressed; and in the late discussion upon tuberculosis at the State House the almost frenzied statements of the laity would be ludicrous did they not reveal at times an underlying selfishness anything but edifying to witness. The opposition we believe to be based upon a false conception of the danger of infection from such institutions when properly regulated.

We have been taught that the chief danger lies in the dried sputa inhaled as dust. In all properly managed hospitals strict attention to the disposal of sputa is now insisted upon, and the recent experiments of Dr. Irwin W. Hance with the dust taken from the rooms of the Adirondack Sanitarium, as well as the tests made by the bacteriologists of the New York City Board of Health, show conclusively how little danger is to be apprehended when the sputum is disposed of suitably.

In the villages near the two largest sanatoria for consumptives in the world, Goerbersdorf and Falkenstein, the death-rate from consumption among the native population has steadily decreased since the foundation of these two institutions.

A statement has recently been made also by an eminent physician and climatologist in Colorado Springs that since the settlement of the town only

twenty cases have been known to begin in the native population, and this in spite of the fact that the place is filled with consumptives from all parts of the world.

Recent experiments, moreover, by Delépine and Ransome in England, have shown that the effect of sunshine upon the bacilli has been to render them inert. James B. Russell, the senior medical officer of health in Glasgow, in a pamphlet entitled "The Prevention of Tuberculosis," lately reprinted by our State Board of Health—a pamphlet to which we have before referred and which in our opinion should be read by every member of the profession—confirms this view by statements which should make us pause before we speak of *danger* from sputa expectorated into the open sunlight, even while we condemn and prohibit the practice of expectoration in public anywhere.

We have the sincerest desire to be just to the advocates of this bill who seek to remove these hospitals from their district, but we maintain that the bill in its present shape is not only unjust (to say the least) but unnecessary. By its very stringency it excites an unwarranted fear in the minds of the community and while its advocates vaguely say that they wish the institutions to be in less thickly populated districts they would make it practically impossible for any individual or set of individuals to establish such a hospital in any town in the State, and this at a time when the importance of special institutions for consumptives is being recognized and acted upon all over the civilized world.

There doubtless exists in the minds of many people a sentimental objection to the neighborhood of any or all hospitals. This objection is not easily combated by facts or by reasoning. It is fomented and increased by such an agitation as has been going on with reference to these hospitals for consumptives in Dorchester. In so far as it exists and in so far as this feeling is encouraged, it does much more to injure the value of real-estate propinquitous to a hospital than any actual influence from the presence of the sick themselves. This sentiment, this property nervousness, is, however, a positive force and must be reckoned with. It is not always enough to reassure real-estate interests to show, for instance, by irrefutable data, as may be done in the case of the Contagious Department of the Boston City Hospital, that there are within a given radius fewer cases of the disease treated at an incriminated institution than in other parts of the city.

Some suitable method for licensing and supervising private hospitals for certain infectious diseases might probably be devised; but great prudence should be exercised in devising such a method—a prudence of which there is no evidence in the bill which has led to these strictures. It would be very easy by ill-considered and hasty measures to do far more injury to the community at large than could be offset by any sentimental or pecuniary satisfaction accruing to any single locality, or to several localities.

AN ALTERNATIVE TO THE WINTER MIGRATION.

THERE was comment in the editorial columns of the last issue of the JOURNAL upon the winter migration to the South, and the suggestion was made for the consideration of some who go away and reap more loss than profit, for the consolation of others who would like to go but cannot, and as a warning to those who undertake to care for the wanderers but sometimes fall short of their promises, that there is an alternative—that alternative is simply to stay at home. For the well-to-do, who form the majority of the travellers, this plan is easy and may be made attractive; for the less well-to-do it is still easier, and at the same time profitable. Few people who have not tried it, with philosophy and ingenuity called to aid, have a realizing sense of how much rest, peace, satisfaction and refreshment can be had in this way.

If about the middle of February or the first of March you are wearied with the exactions of business or what is ordinarily called pleasure, or bored with the routine of the constantly recurring round of daily duties, or disgusted with the extreme changes and buffetings of our overmuch meteorology with the varying ice and slush and mud and dust of the streets; if you have a catarrhal mucous membrane which persists,—send for your doctor and tell him you want a change at home. Let him label you with a suitable disease according to the amount of protection you require from external exactions. Let him order you to stay on one floor, in one room of which, at least, there must be sunshine during part of the day. Have the ventilation and heating carefully attended to. Have your diet changed and regulated. Cast aside the stiff and formal clothing of a perverted civilization—starched shirts and collars, trousers and coats, corsets and starched petticoats, *et id omne genus*. Go to bed as early as you like and get up as late as you like, or as early and as late as your doctor directs. Have a nurse if you are really something of an invalid, or an attendant, at any rate, to wait upon you and respond to your wishes. Collect about you all your favorite old books, and the best new ones. Have some games of chance or of skill. Let your old friends treat you with that kind attention which they will be tempted to show the sufferer. Add to these suggestions anything else which your doctor's ingenuity or your own inventiveness may prompt—it will probably be much—and you who have never tried it will be surprised to find how much refreshment and renewed vigor to body and mind will result from four or five weeks of this kind of change. Try it once and compare it with four or five weeks spent in hurrying to the South and back again.

Those who cannot afford the full programme, may substitute an occasional twenty-four solid hours in bed—a simple therapeutic measure which is not sufficiently resorted to by our overwrought people.

It should not be forgotten that for others who must or will leave home for a comparatively short

period there are places like Newport, the mountains of New Hampshire, the forests of the Adirondacks, which are easy of access, which offer much comfort without crowds, and where a very pure air, free from dust, from rawness or from moisture, may be found.

MEDICAL NOTES.

THE AMERICAN SOCIETY OF NATURALISTS. — The American Society of Naturalists, the American Physiological Society, the American Morphological Society and the American Psychological Association will meet at Cornell University, Ithaca, N. Y., on December 28, 29 and 30, 1897.

A NEW LABORATORY FOR HYGIENE. — A new laboratory for hygiene has been erected and recently opened at the University of Freiburg. It is under the directorship of Prof. M. Schottelius.

THE ARREST OF A DIPLOMA MANUFACTURER. — Frederick Rutland, "Ph.D., M.D." the president of the Wisconsin Eclectic Medical College, an account of which was given in our issue of November 19, 1896, has been arrested in Chicago on the charge of using the mails to defraud.

ALEXANDER J. C. SKENE, M.D., LL.D. — A cablegram from London states that the senate of the University of Aberdeen has decided to confer the degree of LL.D. upon Professor Skene, of the Long Island Medical College, Brooklyn, N. Y.

THE HEROISM OF TWO PHYSICIANS COMMEMORATED. — A stained-glass window has been placed in St. Peter's Church, Fernandina, Fla., by Dr. J. Baxter Upham, in commemoration of Drs. Francis Preston Welford and James Carmichael Herndon who died there during the epidemic of yellow fever of 1877 in the heroic discharge of their self-imposed duty.

ABNORMAL DEVELOPMENT OF THE RIGHT ARM OF A CHILD. — Dr. Goldstein, of the New York Polyclinic, recently presented at the clinic of Professor Fowler, a child who has in her right arm two distinct humeri, each articulating with separate glenoid fossæ of the scapula; three ulnæ, two radii, and three perfectly formed hands. Each of the hands has four perfect fingers and each a perfect thumb. Not only this, but every muscle of every finger and thumb is under the control of the girl, and she can write and perform other operations with any hand. The girl is quite sensitive regarding her deformity. She is bright and studious, but dislikes attending school because she becomes so great a curiosity among her classmates. An expert medical photographer who is employed by the Polyclinic, has recently made some skiagrams of the arm, which plainly show the existence of the distinct bones, humeri, ulnæ, and radii, and the manner in which the three hands are attached to the wrist.—*Medical News*.

TWELFTH INTERNATIONAL MEDICAL CONGRESS AT MOSCOW. — In a letter dated Moscow, February 14th,

the Secretary-General, Prof. W. K. Roth, communicates the following facts for the information of the American physicians who intend to participate in the Twelfth International Congress which is to be held at Moscow from August 19th to 26th. The Transatlantic Steamship Companies refuse one and all any reduction of the usual charges. In their replies, most of which are couched in courteous language, they admit the existence of a trust, or contract, or agreement, which prevents them from lowering their prices; a few are so polite as to express their regrets. Reductions of fares on Russian railroads are expected shortly. The French, Spanish, Swedish and Hungarian railroads promise a reduction of 50 per cent.; so do the Italian for a distance of 500 kilometres; less (down to 30 per cent.) for shorter distances. The Mediterranean lines (Messageries Maritimes, General Italian Navigation Company, Austrian Lloyd) grant from 25 to 50 per cent. The chairman of the American National Committee is not authorized to issue certificates of any kind in favor of congressists. He will try to ascertain, however, in what way their movements may be facilitated, and may receive a reply in the second half of April. Extracts of papers to be read before any of the Sections ought to reach the Secretary-General before June 1st, in order to be printed in the preliminary volume. A special prospectus containing the final details referring to travelling, lodging, festivities, etc., is promised for the near future. It will be communicated at once to the medical journals, and to the press of the country.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, March 10, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 84, scarlet fever 45, measles 183, typhoid fever 5. For the week ending March 17, the following cases were reported: diphtheria 74, scarlet fever 58, measles 146, typhoid fever 7.

A DEPARTMENT FOR CHILDREN.—A hearing was held at the State House on Wednesday, March 17th, on the subject of the creation of a Department for Children, to have charge of the State's minor wards, as recommended by the commission to investigate the charitable and reformatory interests and institutions of the State.

THE ADMINISTRATION OF CITY PUBLIC SCHOOLS.—A meeting of the Women's Education Association will be held in Huntington Hall, Boston, March 25th, at 7.45 P. M., at which "The Administration of City Public Schools," will be discussed by Andrew S. Draper, President of University of Illinois, Champaign, Ill., formerly Superintendent of Instruction in the Public Schools of Cleveland, O.; Charles W. Eliot, President of Harvard University, Cambridge, Mass., and others. A letter will be read from Daniel C. Gilman, President of Johns Hopkins University, Baltimore, Md.

THE WEST END NURSERY AND INFANTS' HOSPITAL.—The fourteenth annual report of this hospital, recently issued, shows that 134 cases have been treated in the wards during the year 1896, and 2,285 in the out-patient department. A lecture-room, which provides seats for 150 people, has been added to the hospital. A training-school for graduate nurses is conducted in connection with the hospital; and since this school was opened in February, 1895, 18 nurses have received diplomas.

TO REGULATE THE MILK-SUPPLY.—The following bill to regulate the milk-supply, accompanies a petition which has been presented to the Massachusetts Legislature by the Bay State Agricultural Society: "The State Board of Health and all local boards of health may make such regulations for the inspection and sale of milk within their respective jurisdictions as will protect the public from the consumption of milk from cows which are diseased or kept in improper sanitary conditions."

THE OLDEST MEDICAL STUDENT.—An ex-minister of the Baptist church has begun the three years' course at the Maine Medical School at Portland. He will be over sixty by the time he receives his degree. He will possess a certain advantage over the average medical graduate, in that his services will probably be not often refused because he looks "so young and inexperienced." Most practitioners, unless blessed with a bald head or a gray beard, are objected to on such grounds until they have arrived at about the age at which this student will begin practice.

NEW YORK.

DEATH OF DR. DUSSELDORF.—Dr. Otto L. Dusseldorf, a retired physician of some prominence, died at the residence of his son, Dr. Louis M. Dusseldorf, in Brooklyn, on March 5th. He was born in Germany in 1829 and came to this country when a boy. Another son of his, Dr. John E. Dusseldorf, is a practising physician at Parkville, Long Island.

DEATH AT THE AGE OF ONE HUNDRED AND THREE.—Thomas Baldwin, said to have been the oldest man on Long Island, died at his residence at Seaford, L. I., on March 4th, at the age of one hundred and three.

DEATH AT AN ADVANCED AGE.—Mrs. Yetta Gerler died on March 1st in a New York tenement-house at the reputed age of one hundred and six years. It is stated that she was born in Poland in 1791, and that she was already married and entertained the French soldiers at her house when Napoleon marched through the country on his way to Russia.

DEATH OF DR. SUMNER A. MASON.—Dr. Sumner A. Mason, a well-known practitioner in the upper part of New York City, died of Bright's disease on March 12th, at the age of fifty-eight. He was born in New Hampshire, and commenced the study of medicine in Boston. He afterwards attended the

medical school of the University of Pennsylvania, and was graduated from there in 1868. He had practised in Harlem for more than twenty-five years.

TO PRESERVE THE ADIRONDACK FORESTS.—A bill has been introduced in the Senate at Albany providing for the carrying out of the suggestions made by Governor Black in his recent message for the preservation of the Adirondack forests. The bill specifies that the Governor shall appoint from the State Land Board and the State Fish and Game Commission a commission of three members, to be known as the Forest Reserve Board, who shall serve without compensation, but are to have their expenses paid, as well as such clinical assistance as may be needed. The Commission is allowed the right of eminent domain to acquire any lands within the definition of the present forestry law. If the Commission cannot agree on a price with the owners or occupants of lands the State Board of Claims shall be the court of final appeal as to the money compensation. One million dollars is appropriated for the purposes of the act.

THE TALLEST WOMAN IN THE WORLD.—It is announced that one of the new attractions of the Barnum and Bailey Show, which is shortly to open its spring season at the Madison Square Garden, is to be the tallest woman in the world, and, if the newspaper reports are to be believed, the tallest person of whom there is any authentic record in existence. She is Ella Ewing, a young woman twenty-four years of age, who was born and has always resided on a farm near Gorin, in Missouri. While her exact height is not given, it is stated that it is very nearly nine feet. Chang, the famous Chinese giant, was eight feet and two inches, and Anna Swan, who was exhibited a few years ago as the tallest woman that ever lived, measured seven feet and eleven inches. In the museum of Trinity College, Dublin, there is a male skeleton measuring eight feet and six inches, and in that of the Royal College of Surgeons of England one measuring eight feet and two inches.

MORTALITY FROM INFLUENZA AND PNEUMONIA.—Influenza has become slightly more prevalent in New York. In the weeks ending March 6th and March 13th the number of deaths reported from it was respectively 15 and 14, against eight deaths in the last week of February, which was the largest mortality from the disease noted up to that time during the present season. There has been no increase in the deaths from pneumonia, which numbered 140 in the week ending February 26th; 137 in that ending March 6th; and 138 in that ending March 13th. These figures compare very favorably with those of the same season in past years. In 1891, for instance, when influenza was widely epidemic, no less than 167 deaths from that disease and 271 from pneumonia were reported in a single week. The mortality from the various zymotic diseases continues small, and that from pulmonary tuberculosis has also been smaller than the average for this time of the year, the deaths

from it numbering 96 in both of the past two weeks. In the same weeks the total number of deaths reported in the city was respectively 824 and 819.

Miscellaneous.

MEDICAL REGISTRATION IN NEW HAMPSHIRE.

A MEDICAL Registration Bill has been passed by the legislature in New Hampshire, entitled "An Act to Regulate the Licensing and Registration of Physicians and Surgeons." The act provides that after September 1, 1897, no person shall have the right to the use of the title M.D., or Dr., or to advertise himself as a physician or surgeon, unless previously registered and authorized, or unless licensed and registered as required by this act.

The examinations for registration are to be conducted by three separate boards of medical examiners, of five members each, to be appointed by the governor and council, and representing the New Hampshire Medical Society, the New Hampshire Homeopathic Medical Society, and the New Hampshire Eclectic Medical Society, from a list of ten nominees submitted by each society to the governor and council for that purpose. The superintendent of public instruction is to be the regent of the State Board of Medical Examiners.

The fee for registration is to be ten dollars, and the applicant must be over twenty-one years of age, of good moral character, and have graduated from a registered college, or satisfactorily completed a full course in a registered academy or high school, or had a preliminary education considered and accepted by the regent as fully equivalent. He must have studied medicine not less than four full school terms, of at least nine months each, in four different calendar years, in a medical college registered as maintaining at the time a satisfactory standard and have received the degree of bachelor or doctor of medicine. The regent may accept as the equivalent of the educational requirements, evidence of five or more years' reputable practice.

The questions for the examinations shall be the same for all candidates, except in the subjects of therapeutics, practice, and materia medica, which shall be chosen from the questions prepared by the board selected by each candidate, in accordance with the school of medicine under which he wishes to practice. Examinations are to be held at least twice annually, and are to be in writing exclusively.

Licenses shall be granted by the regents on receiving from the State board a report that the applicant has successfully passed the examination.

Applicants examined and licensed by other State examining boards registered by the regent as maintaining standards not lower than those provided by this chapter, and applicants who matriculate in a New Hampshire medical school before January 1, 1898, and who receive the degree M.D. January 1, 1903, may, without further examination, on payment of five dollars to the regent, and on submitting such evidence as may be required, receive an indorsement of their licenses or diplomas conferring all rights and privileges of a regent license issued after examination.

The provisions of this act do not prevent the calling of regular physicians practising in other States in consultation, nor do they prevent physicians practising in other States near the boundary lines of New Hampshire, from attending patients in that State.

The provisions of this act do not apply to clairvoyants, or to persons practising hypnotism, magnetic healing, mind-cure, massage, Christian Science (so called); or any other method of healing, if no drugs are employed or surgical operations are performed; *provided*, such persons do not violate any of the provisions of this act in relation to the use of M.D. or the title of doctor or physician.

Every person who is in the practice of medicine or surgery in the State prior to the passage of the act is entitled to registration on payment of a fee of one dollar.

The punishment for infringing the provisions of this act is a fine of not more than one hundred dollars or imprisonment for three months for the first offence, and a fine of not more than \$250 and imprisonment for not less than six months for any subsequent offence, or both fine and imprisonment.

Correspondence.

SOUTHERN GEORGIA AS A WINTER RESORT.

THOMASVILLE, GA., March 9, 1897.

MR. EDITOR:—While spending a few weeks among the pines of Southern Georgia I have been struck with the desirability of this portion of the country as a place of residence for those who find the Northern winter and early spring to be a time of special hardship.

In the treatment of pulmonary and bronchial troubles it is, of course, admitted that suitable out-of-door life is of the utmost importance, and the locality selected should be one where the atmosphere is dry and sufficiently warm to enable the patient to spend nearly all of his time out-of-doors. It is not my intention to compare the various resorts for pulmonary invalids. I simply desire to call attention to a certain section which seems to me to be worth the notice of the medical profession.

The city of Thomasville, where I am at present stopping, contains about 7,000 inhabitants, and is situated 260 miles south of Atlanta. It is 200 miles from the Atlantic and 53 miles from the Gulf of Mexico. The elevation is 330 feet, and it is surrounded by forests of long-leaf pine. The sea atmosphere can only reach it after traversing miles of pine woods, which sift it of its saline elements and lessen its moisture. The soil is a mixture of sand and clay, dries very quickly after a shower, and the natural drainage is excellent. There is almost an entire absence of swamp lands, which always load the air with dampness, and which is so noticeable in many parts of Florida. The average winter temperature is 54°; the average spring temperature is 67°; the relative humidity is 65 per cent.

The dryness of the atmosphere and the soft, warm air, laden with the odors of the pine, have brought this place into considerable repute; and many Northern and Eastern people have erected fine residences and made this their winter home. Their presence changes the character of the place somewhat, and increases its desirability as a place of residence; while largely through their influence the city has been provided with artesian water-works, a system of drainage, and other necessary improvements.

The summers are long, and the heat then must be enervating; but from December to May the climate is delightful, and must be beneficial to those who need to escape from the rigors of a New England winter.

Very truly yours,

LUCIUS W. BAKER, M.D.

METEOROLOGICAL RECORD

For the week ending March 6th, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported 3,021; under five years of age 1,035; principal infectious diseases (small-pox, measles, diphtheria and croup, cerebro-spinal meningitis, diarrheal diseases, whooping cough, erysipelas and fevers) 259; acute lung diseases 610; consumption 365; diphtheria and croup 90; diarrheal diseases 47; typhoid fever 29; whooping-cough 29; scarlet fever 25; cerebro-spinal meningitis 16; measles 14; erysipelas 5; malarial fever 4.

From whooping-cough New York 12, Brooklyn 7, St. Louis 3, Chicago, Boston, Pittsburg, Providence, Nashville, Somerville and Springfield 1 each. From scarlet fever New York 10, Brooklyn 9, Boston 3, Baltimore 2, Waltham 1. From cerebro-spinal meningitis New York 4, Worcester 3, Washington and Somerville 2 each, St. Louis, Nashville, Cambridge, Quincy and Waltham 1 each. From measles New York 10, Brooklyn, Boston, Pittsburg and Worcester 1 each. From erysipelas New York 3, Chicago 2.

In the thirty-three greater towns of England and Wales with an estimated population of 10,992,524, for the week ending February 27th, the death-rate was 19.4. Deaths reported 4,096; acute diseases of the respiratory organs (London) 368, whooping-cough 120, diphtheria 88, measles 65, diarrhea 41, scarlet fever 32, fever 32.

The death-rates ranged from 12.8 in Huddersfield to 24.1 in Norwich; Birmingham 20.3, Bradford 16.5, Cardiff 14.1, Gateshead 21.7, Leeds 20.8, Leicester 20.5, Liverpool 24.0, London 19.0, Manchester 21.2, Newcastle-on-Tyne 18.9, Nottingham 17.2, Portsmouth 15.7, Sheffield 19.3, Sunderland 21.3, West Ham 13.5.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 6, 1897, TO MARCH 12, 1897.

The leave of absence granted CAPTAIN CHARLES WILLCON, assistant surgeon, U. S. Military Academy, West Point, N. Y., is further extended one month and fifteen days, with permission to go beyond sea.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING MARCH 13, 1897.

T. C. CRAIG, surgeon, detached from the Marine Rendezvous, New York, and ordered before retiring board March 16th, then home and await orders.

R. G. BRODRICK, assistant surgeon, detached from the "Constellation," March 15th, and ordered to the New York Navy Yard, March 17th.

JAMES C. PRYOR, commissioned as assistant surgeon from February 27th.

H. E. AMES, surgeon, detached from the "Detroit" and ordered to the "Cincinnati."

D. N. BERTOLETTE, surgeon, detached from the "Minneapolis," ordered home and granted three months' leave.

N. H. DRAKE, surgeon, detached from the "Cincinnati" and ordered to the "Minneapolis."

G. C. HUENARD, assistant surgeon, detached from the "Cincinnati" and ordered to the "San Francisco."

EVENING LECTURES ON CLIMATOLOGY.

By the invitation of the Harvard Medical Alumni Association, Mr. Robert DeC. Ward, Instructor in Climatology in Harvard University, will deliver four lectures on "General Climatology and its Bearing upon Medical Climatology," at the Harvard Medical School on the successive Tuesdays, March 23d, March 30th, April 6th and April 13th, at 8.30 p. m. The profession are cordially invited.

First Lecture, March 23d. "The General Relations of Meteorology and Climatology; the Importance of a Study of Climatology by Medical Men; the Composition of the Atmosphere and the Variations in the Amounts of its Constituents, considered especially in the Relation of these Constituents to Health and Disease."

Second Lecture, March 30th. "The General Distribution of Temperature, Pressure, Winds and Rainfall over the Earth and the resulting Climatic Conditions." This lecture will be illustrated by means of a series of large charts.

NATIONAL CONFEDERATION OF STATE MEDICAL EXAMINING AND LICENSING BOARDS.

The Seventh Annual Meeting of this Confederation will be held in the small banquet hall of the Hotel Walton, at Philadelphia, Monday, May 31, 1897, at 10 o'clock, A. M.

The object of the Confederation is to consider questions pertaining to State control in medicine, and to compare methods in vogue in the several States; the collection and dissemination of information relating to medical education, and to consider propositions that have for their purpose advancement of the standards in the United States. A cordial invitation is extended to all members and ex-members of State medical examining boards, and to physicians, sanitarians and educators who are friendly to the objects named, to attend the meeting and participate in its proceedings.

WILLIAM WARREN POTTER, M.D., *President*.
A. WALTER SUITER, M.D., *Secretary*.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, March 22d, at 8 o'clock.

The following papers will be read:

Drs. W. L. Richardson and G. L. Walton: "A Case of Tem-

pero-sphenoidal Tumor presenting Symptoms suggestive of Abscess."

Dr. E. W. Dwight: "Medico-Legal Aspects of Rupture of the Viscera."

JAMES G. MUMFORD, M.D., *Secretary*, 197 Beacon St.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The Section for Obstetrics and Diseases of Women will meet at 19 Boylston Place, Wednesday, March 24, 1897, at 8 p. m.

Subject, "Gonorrhea in Women." Sociologic side, E. W. Cushing, M.D. Pathology, J. H. Wright, M.D. Treatment, Edward Reynolds, M.D.

F. W. JOHNSON, M.D., *Chairman*.
C. H. HARE, M.D., *Secretary*.

AMERICAN PEDIATRIC SOCIETY.—The ninth annual meeting of this Society will be held at Washington, D. C., May 4, 5 and 6, 1897. One session is to be devoted to the demonstration of apparatus and pathological specimens.

WILLIAM P. NORTHRUP, M.D., *Chairman of Council*,
57 East 79th Street, New York.

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.—The fourth session of this Congress will be held in Washington, D.C., May 4, 5 and 6, 1897. The meetings of the Congress will be held in the Columbia Theatre, corner of Twelfth and F Streets, N. W.

On Tuesday, May 4th, a Business Meeting of the Congress will be held from 1.30 to 2 p. m. From 2 to 3.30, there will be a general meeting of the Congress under the direction of the American Ophthalmological Society, Subject, "The Gouty and Rheumatic Diatheses and their Relation to Diseases of the Eye." From 3.30 to 5 p. m., there will be a general meeting under the direction of the American Otological Society, Subject, "Otolgy in its Relations to General Medicine."

On Wednesday, May 5th, from 2 to 5 p. m., will be held a general meeting of the Congress, under the joint participation of the Association of American Physicians, the American Physiological Society and the American Pediatric Society, Subject, "Internal Secretions considered in their Physiological, Pathological and Clinical Aspects." At 8.15 p. m., Address by the President of the Congress, Dr. William H. Welch, Professor of Pathology in the Johns Hopkins University, Baltimore, Md., to be followed by a Reception by the President, at Rauscher's, corner of Connecticut Avenue and I Street.

On Thursday, May 6th, from 2 to 3.30 p. m., there will be a general meeting of the Congress, under the direction of the American Orthopedic Association, Subject, "Deformities of the Hip-Joint, especially Congenital Dislocations." From 3.30 to 5 p. m., will be held a general meeting of the Congress, under the direction of the American Surgical Association, Subject, "The Classification of Acute General Peritonitis: The Prognosis and Treatment of the Different Varieties."

WM. H. WELCH, M.D., LL.D., *President*, Baltimore, Md.
WM. H. CARMALT, M.D., *Secretary*, New Haven, Conn.

HARVARD MEDICAL SCHOOL.

EVENING LECTURES.

The next Thursday evening lecture will be given by DR. F. E. CHENEY, on March 25th, at 8 p. m. Subject, "Injuries of the Eye." The profession are invited. The lectures announced early in the season to be given by Prof. J. C. Warren will be omitted.

BOOKS AND PAMPHLETS RECEIVED.

Gonorrhea, Its Ravages and Its Prophylaxis. By Albert H. Burr, Ph.B., M.D. Reprint.

Sixteenth Annual Report of the State Board of Health of New York. Transmitted to the Legislature February 17, 1896. New York: Printed by the State. 1896.

The Year Book of Treatment for 1897; A Critical Review for Practitioners of Medicine and Surgery. By twenty-six English authors. Philadelphia and New York: Lea Brothers & Co. 1897.

The Medical Annual and Practitioner's Index; A Work of Reference for Medical Practitioners. By thirty-nine English and American contributors. Fifteenth year. Bristol: John Wright & Co. New York: E. B. Treat. 1897.

Organ Diseases of Women, Notably Enlargements and Displacements of the Uterus, and Sterility, considered as Curable by Medicine. By J. Compton Burnett, M.D., Author of "Tumors of the Breast," etc. Philadelphia: Boencke & Tafel. 1897.

The American Year-Book of Medicine and Surgery, being a Yearly Digest of Scientific Progress and Authoritative Opinion in all Branches of Medicine and Surgery, drawn from Journals, Monographs and Text-Books, of the leading American and Foreign Authors and Investigators. Collected and arranged with critical editorial comments by twenty-seven American Authors under the general editorial charge of George M. Gould, M.D. Profusely illustrated. Philadelphia: W. B. Saunders. 1897.

Original Articles.

THE TREATMENT OF BRONCHIAL ASTHMA.¹

BY FREDERICK I. KNIGHT, M.D.

THE term "asthma" has been applied to every form of dyspnea, paroxysmal or not, which is known to medicine.

What is properly so called at the present time is a paroxysmal difficulty in breathing due to temporary obstruction of the bronchial tubes.

The cause of this obstruction is now usually attributed to spasm of the bronchial muscles, or hyperemia and swelling of the bronchial mucous membrane, or both. In a certain number of cases the onset and termination of the attack are both so sudden and so free from catarrhal products as to indicate that it is purely spasmodic; on the other hand, in a much larger number of cases the preliminary cough and subsequent expectoration of Curschmann's spirals from the bronchioles indicate an obstructive affection of the bronchial mucous membrane.

The mechanism of an attack is varied, and much needless controversy has arisen from the fact that the discoverer of it in one case has too often endeavored to make this account for all other cases.

We have several factors to take into consideration in looking for the cause and later for a guide to the rational treatment of this affection. It may be due to one morbid condition, or to a combination of several. The principal conditions, which either alone or in combination, may be concerned in an attack of asthma are:

- (1) Disease of the lungs or bronchi.
- (2) Pressure on, or hyperesthesia of the vagus nerve.
- (3) Direct irritation of the bronchial mucous membrane.
- (4) Some peripheral morbid condition acting by reflex on the bronchi.
- (5) Toxemia.

Exactly how often an attack may be caused by one of these conditions, or to what extent a combination is always present, is not determined; but there is undoubtedly in a very large number of cases an abnormal condition of the lungs or bronchial tubes, which attracts the reflex. Hyde Salter and Berkart claim respectively that eighty and ninety per cent. of cases of asthma in the young date from some inflammatory affection of the lungs.

(1) Disease of the lungs or tubes, often the result of some acute inflammatory affection, makes the tubes prone to spasm or hyperemia. In case such morbid condition exists, the patient may probably have asthmatic attacks from this local cause of irritation without the assistance of any other factor, but is especially liable to attacks in case of the presence of either of the other factors at the same time.

(2) Louget, C. J. B. Williams, Lazarus and others have demonstrated experimentally that spasm of the bronchi could be produced by direct irritation of the lungs or vagus. So an attack of asthma may be produced by the pressure of tumors or enlarged glands on the vagus. Of course, an attack would be favored by a morbid condition of the lungs at the same time.

The phenomenon being produced through the ner-

vous system, hyperesthesia of this system is naturally oftentimes a factor in the production of it, though it is doubtful if there are any purely nervous cases, idiopathic, so called, in which no other factor is present except vagus-hyperesthesia. Certainly the cases in which we can discover no organic cause are becoming fewer and fewer.

In the few cases in which the exciting cause is psychic, other factors are, as a rule, probably present.

(3) The inhalation of mechanical irritants, dust, pollen, fumes of sulphur matches, etc., is the exciting cause in many cases. Some odors of flowers, animals, etc., act as direct irritants, others come rather under the toxic class.

(4) The sources of reflex from peripheral irritation are various, the nasal and gastric being best known, but may occur in many other regions. They may be traumatic. Nasal surgery, like that of other regions, has been wonderfully extended and improved in recent years, and many cases of asthma arising from irritation or obstruction in this field have been discovered and cured, and not unnaturally the nose has assumed an undue prominence as a factor in the production of asthmatic breathing.

Digestive derangements have long been known as excitants of the paroxysms, and are still potent.

(5) Under toxic causes we find the renal, gouty and malarial cases, as well as those due to carbonic acid, lead and other chemical poisons. The gouty and malarial origin has been too often overlooked. Some of my hearers may remember the cases of this kind reported by Beverly Robinson at the meeting of the American Climatological Association in this hall in 1889.

When we reflect upon this brief outline of some of the factors which may be concerned in producing an attack of asthma, it may be seen that the question of treatment is by no means a simple one. The relief of the paroxysm may be easy, but the prevention of recurrence requires a careful study of possible causes, as indicated above.

Berkart in his monograph which calls attention to the large number of cases of asthma in which antecedent pulmonary disease will be found, says of his study of the affection that "little perspicacity is needed to discover that the prevailing obscurity in the nature and treatment, primarily and mainly, arose from the exclusive attention bestowed upon the dyspneal paroxysms, whereas their constant antecedents and sequelæ, which form the life history, as it were, of the disease, were either neglected or erroneously interpreted.

The treatment of the paroxysm, however, is often what first demands our attention. We will consider this first, and afterwards the treatment in the interval between the attacks, including the radical treatment of the underlying cause, when that is possible.

The first thing which demands brief consideration, when called to a patient in a paroxysm, is whether it may be possible to remove at once one of the factors, and thus perhaps put an end to the attacks. If the patient has had attacks before, he has probably learned to avoid direct irritants, like dust, odors, etc., which are most evident, so that it is not worth while to spend much time during a paroxysm in hunting for these; but some peripheral source of irritation by reflex may be seen at once, as, for example, a nasal polyp or an overloaded stomach, the relief of which

¹ Read before the Boston Society for Medical Improvement, December 14, 1896.

will end the attack for the time being. So carbonic-acid poisoning may be relieved by exercise of the lungs in fresh air.

In most cases, however, some medical treatment will be called for. We probably cannot determine at once whether we have predominant spasm or hyperemia and swelling of the mucous membrane, but practically the treatment of the one is not antagonistic to the other. The efficient remedies are those which reduce the irritability of the nervous system, relax spasm, thin the mucous secretion, and even produce a kind of bronchorrhea.

As any patient with asthma may have an underlying condition very difficult of removal, and may require frequent repetitions, at longer or shorter intervals, of the treatment of the paroxysm, it is important to use, unless absolutely necessary, only such remedies as may not incapacitate the patient for the next day's duties, and such as will not be likely to inaugurate the drug-habit. If there is evidence of an underlying condition of bronchitis it is well to put the patient on the internal use of potassium iodide at once. The simplest remedies, and those attended with the quickest relief, if relief comes at all from them, are those which are taken by inhalation. They all of them act more or less by exciting secretion, and most of them by relaxing spasm also. Some act well in one case, and some in another; and those remedies which have most success are usually combinations of various drugs. Nitrate of potassium, stramonium, belladonna, hyoscyamus and arsenic are found in variable numbers and proportion in most of the powders and cigarettes in the market. One drug or one combination affects one, and another, another; and only trial will decide which is best for any particular case.

If no relief comes from such inhalations then the milder internal remedies may be tried. Phenacetin and other remedies of its class may give relief. Strong coffee or hot alcoholic drinks may suffice. If necessary we proceed to less simple measures, such as the inhalation of ethyl iodide, or the amyl nitrite, or the internal use of nitro-glycerin. The latter drug is very efficient in the relief both of spasm and of hyperemia. A large proportion of cases recover quickly on the combined use of potassium iodide and nitro-glycerin. Unfortunately the system soon becomes very tolerant of the latter, and the doses have to be constantly increased.

If still more powerful measures are called for, then those agents must be used which have a profound effect in diminishing the irritability of the nervous system. The hypodermic injection of morphia and atropia is one of the best, and will usually give relief, though I have seen a case, which always resisted morphia, yield readily to the inhalation of chloroform. The use of chloral, which often gives speedy relief, is to be avoided, if possible, on account of the very depressing after-effects. I must utter again a warning note against the use of any but the simpler remedies for the paroxysm unless absolutely required.

We now come to the treatment of patients in the intervals, to the treatment of the underlying conditions which, singly or combined, cause the attacks.

The first factor to which I have directed attention is the condition of the lungs and bronchi. As I have said, a previous inflammatory condition exists in many, according to some authorities in a very large

majority of cases. In some we have physical evidence of a chronic bronchitis. It is in these cases especially that the potassium iodide gives so much relief, either as an absorbent, or as an alkali, increasing and thinning the bronchial secretion. Certain it is that this remedy when properly given relieves and cures more asthmatic patients than any other one. Sometimes, no doubt, the relief comes from its action on enlarged glands which compress the vagus.

The potassium iodide should be given in doses from five to sixty grains, if needed, for a thorough trial, unless contraindicated. The syrup of hydriodic acid is sometimes useful, but needs to be given in larger doses than those usually prescribed. The dose should be from a dessertspoonful to a tablespoonful. This is not nearly so efficacious as the potassium iodide.

In case of derangement of the stomach I have found the sodium iodide and strontium iodide better borne. I have lately used the latter a good deal, and find that it is much more acceptable to the patient. All of the iodides should be given largely diluted on an empty stomach. I usually give them ten or fifteen minutes before meals. The continued use of a vasomotor depressant, such as one of the nitrites either alone or with an iodide, when that is indicated, is of great benefit. Nitro-glycerin may be used, but the nitrite of sodium has a more lasting effect. The dose of this drug given in many books is too large, one or two grains being usually enough, and large doses dangerous.

In case of emphysema, strychnia is useful — also expiration into rarefied air.

The second factor on my list is pressure on or hyperesthesia of the vagus nerve. As I have said, potassium iodide may act favorably on enlarged glands which press on the vagus. The same is true of arsenic, which is also a good nerve tonic and is said to act favorably on the bronchial mucous membrane. Practically arsenic has shown itself of great value. Other nerve tonics are indicated, especially quinine, which in large doses may even abort a paroxysm.

The removal of the direct irritant is possible in many cases, and efficacious in preventing the paroxysms, though hyperesthesia of the nervous system may be a prominent symptom. Feather beds, animals, kerosene lamps, arsenical wall-paper, various kinds of dust and many other objects, when found to be excitants, may be easily removed; but others cannot be, and yet it may be possible to remove the patient from them, as in the asthma of autumnal catarrh or other less defined climatic or atmospheric conditions. Certain regions of this country are known to be exempt from all of the symptoms of autumnal catarrh, asthma included.

In other cases the atmospheric condition which provokes the attack is not so well defined, and relief may be obtained only after repeated changes. The slightest change in location will sometimes give relief. More patients get relief by going from the country to the city than from the city to the country. A curious feature of the immunity of location is that in time it often fails, and another change is necessary. I remember the case of a physician who changed his residence and practice several times during his life, on account of asthma, and who finally got relief by going back to the place from which he started.

In making any change consideration must, of course, be paid to the probable effect of the climate on other

factors, for example, on the condition of the lungs and bronchi and on the nervous system.

Of peripheral origin of reflex irritation the nasal region furnishes a good many cases, so many that the digestive and other important regions have recently been too little investigated. The nasal polyp is easily recognized, and so usually are other morbid conditions which are likely to set up reflex action. Contact of a turbinate bone with the septum may be a source of great irritation, less frequently chronic disease of the turbinates, tonsils, pharyngeal-adenoid, etc. The whole naso-pharynx must be put in as healthy a condition as possible.

As I have just stated, digestive derangements have been in recent years far too little considered. Indigestible food, especially when taken at night, is often the cause of an attack; though other factors may be present, it is this added irritation which determines the paroxysm. The digestive tract is so much under our control that it is very important to regulate the quality and quantity of food, and time of meals, and perhaps also to treat some evident morbid condition. The intestinal tract must be investigated, especially for parasites. The sexual system and possible trauma must be considered.

No study of an obstinate case is complete without the consideration of toxemia. Lead and arsenic should be sought, and especially should the lithemic condition be looked for. An anti-lithic diet, regimen and medicine will relieve many otherwise incurable cases. The same is true of the appropriate treatment of malarial cases. In cases of renal dyspnea due to uremic intoxication there is sometimes an apparent increase of suffering, due perhaps to spasm of the bronchi, as indicated by sonorous râles, but it is better not to consider these cases under the head of bronchial asthma such as we have been considering.

It will be seen from this brief sketch that many morbid conditions may be concerned directly or indirectly in the production of a case of bronchial asthma, which act singly or combined, and that the treatment should be directed towards the removal of as many as possible of these conditions. The result will be more satisfactory the nearer we get to a removal of all of them.

The more of these factors we can diagnosticate the simpler may be our treatment. Grand combinations of many drugs either for inhalation or internal use are to be avoided unless single remedies fail. Patent and proprietary medicines and treatment of patients at a distance without examination for differential diagnosis must naturally be compound, including everything known to be "good"; but when a physician can have his patient under observation this can often be avoided.

In conclusion, I will add a few words in a general way as to the selection of a climate for asthmatics. As I have already said, the influence of climate is often very subtle, yet if we proceed on the same lines as I have suggested for medicinal treatment, of considering what factors we may influence by change of climate, we may yet often guide a patient successfully. Can we remove him from some direct irritant, as in the hay fever cases? Shall we find a climate which will fortify or calm a hyperesthetic nervous system? Or shall we (which is perhaps oftenest required) put him in a climate which will act favorably on his bronchial inflammation? If we wish to do the latter, a

dry, elevated region is indicated if the bronchitis is moist, but a warm, moist climate will probably be better if the bronchial mucous membrane is dry and irritable. As in all other means of treatment the nearer we get to an exact diagnosis of the exciting and underlying causes of asthma, the more intelligently and successfully will we be able to advise in regard to change of climate.

CASES OF GALL-STONE SURGERY.¹

BY J. W. ELLIOT, M.D.

I WOULD like to arouse the interest of this Society, composed as it is of both physicians and surgeons, in biliary lithiasis.

(1) Because these cases are sadly neglected, or treated by solvents when there is no known medicine that will dissolve gall-stones.

(2) Because modern surgery offers a first-rate chance of cure. The general mortality in these cases was about 17 per cent. in 1893, but I feel sure that this figure is too high. My own operations for gall-stones now number 16, without a death.

When we remember that ligation of the gall-ducts in animals² causes a destructive process in the liver, and that the liver is capable more than any other organ of regeneration when the duct is reopened, we have the scientific basis for a great surgical opportunity which has not been disappointing. The obvious chance for improvement is in early diagnosis and early operation.

The cases I have to report to-night were operated on in my last hospital service. They illustrate various conditions due to the presence of gall-stones and the corresponding operations for relief. In five of the cases the trouble was limited to the gall-bladder and cystic duct. In one case the stones had obstructed the common duct. Of the five cases in which the gall-bladder alone was affected, in two it was possible to close the gall bladder with sutures at once, and in one the gall-bladder was in a state of acute inflammation simulating acute appendicitis. In the latter case the gall-bladder was drained at first and extirpated at a later operation.

CASE I. Chronic inflammation of gall-bladder. Immediate suture after removal of a large stone.

The patient, a married woman, aged fifty-three, entered the Massachusetts General Hospital November 16, 1895.

History.—She represents the fourth generation on her mother's side afflicted with gall-stones. One sister died of gall-stones. There is a family history of gout on her father's side. She has had chronic dyspepsia for years. From 1870 to 1884, she had a great many attacks of pain referred to the epigastrium, and was often slightly jaundiced either during or after these attacks. In 1884 she became a chronic invalid, and took the "cure" at Carlsbad with great relief. This was repeated in the following year. Since then, up to 1895, she has been treated with Carlsbad salts and diet.

One year ago she was laid up for three months with an attack. A very severe pain in the region of the gall-bladder was continuous for six days, requiring opiates. After the attack there was great soreness and tenderness in that locality. The pain would shoot

¹ Read before the Boston Society for Medical Improvement, December 14, 1896.

² Nasse: Arch. für klin. Chir., 1894, H. 48.

through the back up the right chest to the shoulder. There was frequent vomiting while the pain lasted. During October she had three attacks lasting three or four days. The stools have never been clay-colored, nor has jaundice been extreme.

On examination an indistinct mass could be felt in region of the gall-bladder. Temperature 99°, pulse 90.

Operation (November 19th). — When the gall-bladder was exposed it was found adherent to the intestine and omentum. It contained four ounces of clear mucous fluid and a stone as large as a pigeon's egg. The stone had no facets. The ducts were sounded and palpated, but no more stones were found. A part of the gall-bladder wall had become ulcerated by the pressure of the stone; the rest was moderately thickened, but tolerably normal. The ulcerated part was cut out, and the gall-bladder was then closed tight with two rows of stitches. The abdomen was closed, leaving a gauze wick down to the sutures in the gall-bladder.

The patient made a good recovery, the wound healing by first intention. She left the hospital on December 16th.

In December, 1896, more than a year after the operation, she was known to be well.

CASE 11. Severe colic of gall-bladder. Immediate suture after removal of several stones from the cystic duct.

The patient, a married woman, aged thirty-two, entered the hospital May 27, 1896.

History. — Eight months previous to entrance she had had an attack of very severe pain in the epigastrium and right hypochondrium lasting several hours. There was vomiting and slight jaundice, but no chills. In the last eight months had had ten or twelve attacks at intervals of one to three weeks. Each attack seemed more severe than the previous one. The last attack, three weeks before entrance, lasted thirty hours. There was pain, vomiting and jaundice, followed by soreness in the right side.

On examination the temperature was 99.8°, pulse 80. The patient was very large and enormously fat, so that there was no hope of feeling the gall-bladder. Tenderness in the right hypochondrium was the only physical sign present.

Operation (May 29th). — The gall-bladder was found to be rather small. Palpation disclosed a small stone in the cystic duct. When the gall-bladder was opened an ounce of dark bile flowed out. Six small, light-yellow mulberry stones were removed by milking the cystic duct and gall-bladder with the hand outside. No stone was felt in the hepatic or common ducts. The gall-bladder showed no signs of inflammation and no adhesions. The opening in its fundus was closed with a double row of sutures. The abdomen was closed tight without drainage. An umbilical hernia the size of a pigeon's egg was also closed.

Recovery was uninterrupted and complete. Discharged June 21st.

A letter, dated July 29th, states that the patient was restored to perfect health.

CASE 111. Adhesions of gall-bladder, the result of a former operation, removed.

The patient, a married woman, aged thirty-eight, entered the hospital for the second time April 1, 1896.

On July 6, 1894, I had removed several large stones from the gall-bladder and cystic ducts, closing the gall-bladder with sutures and stitching it to the ab-

dominal wall. She was much relieved after the operation and gained twenty pounds in three months. Since then her old attacks of pain had returned, and had increased in frequency and severity. She had become very neurasthenic.

Nothing found on examination except tenderness in epigastrium and right hypochondrium.

Operation (April 6th). — The gall-bladder was found attached by numerous adhesions, the fundus being adherent to the abdominal wall so that it was drawn out. The duodenum was adherent to the edge of the liver and the gall-bladder to the lesser omentum. When all the adhesions were freed, the gall-bladder was found to be entirely normal, no thickening and no stones.

Recovery was rapid, and followed by absolute relief.

CASE IV. Acute inflammation of the gall-bladder. Cholecystotomy, later cholecystectomy.

The patient, male, aged thirty-one, was sent to the hospital as a case of appendicitis. On arrival he had a temperature of 100.4°, with a tense and swollen abdomen, and complained of severe pain in the right side.

History. — He had been very thin for ten years. For the last two years had suffered from digestive disturbances, pain, gas formation and vomiting. About two years before entrance he had had two attacks of severe pain in the "pit of the stomach"; since then he had had fifteen slight attacks; he had never been jaundiced. The present attack began ten days ago, with a pain in the small of the back which gradually came forward to the pit of the stomach. Four days before entrance he was obliged to go to bed, with nausea and vomiting and a very severe pain in right abdomen. The abdomen became very tender and he felt feverish, but had no chill.

On examination the abdomen was found to be tense and generally sensitive. The right rectus muscle was rigid in the region near the ribs, but much less so in the pelvic region. At the border of the ninth right costal cartilage a tender swelling could be indistinctly felt through the rigid rectus muscle. A diagnosis of acute inflammation of the gall-bladder was reached.

Operation (March 6th). — A longitudinal incision was made from the ninth right costal border, downward three inches, into the abdomen. The gall-bladder presented. Its walls were deep red, almost black. It was glued to all the surrounding organs by recent adhesions. A canula drew clear fluid at first, but later it came yellowish and thick. The peritoneal cavity being walled off with gauze, the gall-bladder was freely incised. A yellowish, thick, foul-smelling fluid came out — apparently pus mixed with dark, fine crystals. The bladder wall was dark, thick and friable, almost in a sloughing condition. I should have removed the gall-bladder at once but for fear of infecting the peritoneal cavity in breaking up the adhesions.

The gall-bladder was washed out with an antiseptic solution. No stones came out, and the ducts were not examined. It was partially surrounded with gauze and stitched to the abdominal wound as well as its friable condition would permit. A drainage-tube and a piece of gauze were placed inside the gall-bladder. The temperature fell to normal, and the abdomen became soft in a few days.

The recovery was uninterrupted.

On April 24th the patient was looking well and felt well. There was a sinus into the gall-bladder, which would close for twenty-four hours and break out again, discharging a greenish mucus. The patient was discharged much relieved.

May 1st. The patient appeared, complaining that the wound had been closed for thirty-six hours, which caused him great pain in the gall-bladder. The sinus was opened with a knife allowing the escape of two ounces of clear mucoid fluid, giving immediate relief.

May 4th. The patient re-entered the hospital, complaining that the continual closing of the sinus gave him much trouble and pain. It was quite evident from the collecting of the clear, mucous fluid, that the cystic duct was closed, and that the gall-bladder already diseased would be liable to another acute inflammation. Removal of the gall-bladder was therefore advised.

Operation (May 7th). — The old scar was cut out, and the gall-bladder and sinus freed from the abdominal wall. It was bound firmly to all the neighboring organs by adhesions. The dissection was slow and difficult. A stone, the size of a cherry, was found blocking the cystic duct. It was in a pocket off the duct, and was completely covered with mucous membrane so that it felt like a fibroma. The separation of the bladder was finally completed after much difficulty, especially on the side towards the liver. The bleeding surface of the liver was packed with gauze.

Recovery was rapid and uneventful.

Since the last operation the patient has had no pain and no digestive disturbance. He has gained flesh, and was in perfect health December 16th, seven months after operation.

CASE V. Acute symptoms in a chronically inflamed gall-bladder; cholecystotomy.

The patient, a married woman, thirty-six years old, entered the hospital May 26th.

History. Eight years previous to entrance she had had an attack of inflammation of the bowels on the right side. Eight days before entrance, without previous symptoms, she was waked in the middle of the night with pain, and discovered a bunch in her right side. She went to work the next morning, but vomited. The vomiting continued for twenty-four hours, very severe. The pain also continued to be severe.

On examination the general condition was found to be poor; patient thin and pale. Temperature 99°, pulse 88. The abdomen was not rigid or distended. In the right side there was a tense, smooth, movable mass, size of a cocoanut, extending from the costal margin to the median line, below navel, and to the lumbar region. It descended on inspiration, and was slightly dull on percussion. On May 29th, it was aspirated and three ounces of yellowish, quite clear mucous fluid evacuated — evidently from the gall-bladder.

Operation (May 30th). — On opening the abdomen a large, chronically inflamed gall-bladder was seen. A stone was easily felt in the cystic duct, and others in the gall-bladder. About twelve stones were removed. The gall-bladder was large, thick walled, deep-red in color, and was firmly adherent to the liver. It was thought best to remove it, but the adhesions proved so dense and the patient's condition so poor that the removal was abandoned; the opening in the fundus was stitched to the peritoneum in the lower angle of the

wound, and the gall-bladder was drained. In examining the ducts it was noticed that there was no kidney in the right side but that there was a mass of about kidney consistency lying across the vertebral column at about the level of the pancreas, probably a horse-shoe kidney.

The wound healed by first intention, leaving a sinus which closed in about six weeks. A cough appeared, and tubercle bacilli were found in the sputum. She left the hospital July 22d.

CASE VI. Cholemia and cholangitis. Stones removed from gall-bladder, cystic and common ducts; suture of the common ducts; and cholecystotomy.

The patient, a married woman, aged forty, entered my ward of the hospital February 19, 1896.

History. — For a long time she had had several attacks yearly of gastric distress, with vomiting, but no sharp pain. Had malaria (?) in July and August, 1895. From November, 1895, had had distress after meals and vomiting daily for several weeks, usually two or three hours after meals. No abdominal pain. For last two months symptoms somewhat less distressing. Became jaundiced about two months before entrance; this had gradually increased. Urine had been dark and she had suffered from pruritis. She gave up work two months ago, and since then had lost strength and twenty pounds in weight. Had occasional headache.

On examination the patient appeared to have a dull expression. She was well developed but thin. Deep icterus of skin and conjunctivæ; dark circles about the eyes. Abundant small papules and crusts all over the body, partly the result of itching and scratching. No glands. Considerable enlargement of liver. There was an indefinite resistance just below the edge of the liver. The vomitus contained free hydrochloric acid. The stools were clay-colored. Blood-count as follows: reds, 4,520,000; whites, 13,000; hemoglobin, 60 per cent.

Operation (February 25th). — On making the usual incision the gall-bladder was found covered with adhesions so as to obliterate all landmarks. The stomach was so adherent to the gall-bladder as to give the appearance of malignant disease. When the bladder was finally freed and opened, it was found full of soft, small stones and a thin, brown fluid. The cystic duct was much dilated and filled with stones. The finger was passed down through the cystic duct into the common duct where more stones were felt. In attempting to remove these stones the common duct was torn open. The stones were then easily removed through the tear, and a sound was passed into the intestine, showing that the duct was clear. Stones were also pushed down from the hepatic duct through the opening in the common duct. The tear in common duct was then closed with a double row of sutures. The opening in the gall-bladder was stitched to the abdominal wound and drained. A gauze drain was left in region of common duct. The patient suffered considerable shock from the operation, but soon rallied, and made a good recovery. No bile leaked from the wound of common duct.

March 2d. Constant drainage of bile. Stools clay-colored. Less jaundice.

March 11th. Ox-gall was given in the hope of stimulating the flow of bile and improving digestion.

March 19th. Stools have gradually become normal in color. Discharge from gall-bladder has gradually ceased. Skin clearing up.

March 29th. Great improvement in every way.

April 3d. Sinus healed. Discharged.

June 9th. Three and one-half months after operation, patient seen and found to be well in every way.

In a former paper,⁸ read before the American Surgical Association in 1895, I expressed the opinion that cholecystotomy had become too much the routine practice, that immediate closure of the gall-ducts and the gall-bladder by suture was the operation of choice, and could, as a matter of fact, be done in a large proportion of cases. The advantages of immediate suture over tedious drainage are obvious, provided it can be done with safety to the patients. My cases of immediate suture have all been successful, and they now comprise five cases of suture of the gall-bladder, one case of suture of the hepatic duct, and two cases of suture of the common duct.

Case IV was evidently an acute infection of the gall-bladder, and was on the point of causing general peritonitis. The symptoms and conditions found were almost exactly like an appendicitis; furthermore the operation for drainage, followed by removal of the organ in a quiescent stage of the disease, carries out the analogy to appendicitis.

I have changed my views somewhat in the last year in regard to removal of the gall-bladder. I now believe it is better to do cholecystectomy instead of cholecystotomy in cases where the gall-bladder has been the seat of a destructive inflammation as evidenced by extensive ulceration or greatly thickened walls, or extensive adhesions to the surrounding organs, or the condition known as "contracted gall-bladder." In cases of acute infection it should remain a matter of judgment in each particular case whether it is safer to do a cholecystectomy at once, or a cholecystotomy as an emergency operation, and a cholecystectomy later, as in Case IV. I also think that in case of a recurrence of stones in the bladder, cholecystectomy should be done. Not that removal of the gall-bladder will absolutely prevent the formation of stones, but it will do away with one important condition which favors their formation, namely, a diseased gall-bladder.

HYDROCELE MULIEBRIS, WITH THE REPORT OF A CASE.¹

BY CHARLES G. CUMSTON, B.M.S., M.D.,
Assistant Professor of Surgical Pathology, Faculty of Medicine,
Tufts College, etc.

Cysts of the canal of Nück are not frequently met with, and the report of a case operated on by the writer a short time since may not be without interest, followed by a few remarks on the pathology of the disease.

The patient, Mrs. O. H., age sixty-three, was kindly referred to me by Dr. L. in April, 1896. The patient stated that she had always been in very good health, with the exception that she was rather of a nervous temperament. The menses appeared for the first time at the age of fourteen and one-half years, and were always regular up to the time of the menopause, which occurred at the age of fifty-two. They were not attended by any pain, and appeared to have been in every way normal. The patient had had

three children at term and two miscarriages. Fifteen years previously the patient had first noticed a small lump in the right groin which was about the size of a cherry. The only symptom to which this small tumor gave rise was a dragging pain in the groin when the patient had walked a great deal and was tired. About two years previously the patient had slipped on an icy sidewalk and fell, but this fall only produced slight nausea, which was due to a pain which was started up in the region of the tumor. After this accident the patient noticed that the tumor had increased in size.

She consulted a surgeon, who informed her that she had a hernia, and ordered a truss; and, according to the patient's statement, before the latter was applied, the so-called hernia was reduced. The wearing of the truss irritated the skin over the tumor to a certain extent, and obliged the patient to occasionally leave the support off; and two weeks previously to seeing the writer, after she had removed her truss she noticed that the tumor had increased considerably in size and was painful to the touch. A physician was sent for, who found the tumor irreducible, and sent for another doctor, who gave ether; and, according to the statements of this gentleman, they reduced the bunch and applied the truss. But finding that the seat of the tumor was a source of great pain to her, the patient consulted Dr. L., who kindly gave the case over to me.

The patient was a well-nourished woman, intelligent and apparently in very good physical condition. Examination of the tumor showed a lump in the left groin, situated in just the position that would be occupied by an inguinal hernia and about the size of a large hen's egg. Standing up or lying down in no way changed the shape of the lump, and there was no impulsion when the patient coughed. Palpation showed an elastic tumor which could not be reduced into the abdomen. The Trendelenburg position did not facilitate reduction of the tumor. Percussion gave a dullness over the tumor. Skin moved freely over the growth.

From the history of the case and from the fact that the patient said that the tumor had been reduced on several occasions, I was inclined to admit the diagnosis of an inguinal hernia, which had probably become inflamed and was adherent to the inguinal ring, thus preventing its entrance into the abdominal cavity; but I had never felt such an elastic, tense tumor before in the region, and I doubted the correctness of my diagnosis.

The patient entered the Elliot Hospital, and the operation was performed the following morning. An incision through the skin was carried over the long axis of the tumor, the subcutaneous fat carefully incised, and the hernia sac was searched for, but none was to be discovered. With a Kocher's director the tumor was separated from the surrounding tissue, and suddenly an apparently cystic growth came up into the wound. Dr. Maurice H. Richardson, being at the hospital at that time, was good enough to see the case and confirm the diagnosis that I had already made, namely, a cyst of the canal of Nück.

The tumor was connected in the abdominal ring by a long pedicle. It was transparent, its surface lobulated and over which ran a certain number of small vessels. The tumor was perfectly transparent; but in order to be sure of my diagnosis, a puncture was made; about three ounces of a clear, straw-colored

¹ Read before the Suffolk District Medical Society, Section for Obstetrics and Gynecology, December 23, 1896. Discussion in Journal of March 18, 1897, p. 264.

⁸ Annals of Surgery, July, 1895.

liquid escaped and the tumor collapsed. The cyst was then drawn up out of the incision as far as possible, traction being made on the pedicle, and a stout silk ligature tied around the base, after which the tumor was severed from its attachment by scissors.

The wound was sutured with silk and an occlusive dressing applied. The subsequent events were of the simplest. There was no elevation of the temperature; the sutures were removed at the end of a week; and the patient left the hospital ten days after the operation in excellent condition.

Dr. L. has had the goodness to inform me recently that the patient is in every respect in the best of health, and that there is no complication at the site of the incision.

For many years, and even now, a certain number of surgeons refuse to admit the existence of cysts of the canal of Nück; but having carefully gone over the literature of the subject, and from the case here reported, the writer has no hesitation in believing that this condition is an actuality. As we all know, the round ligament is covered during fetal life by a prolongation of the peritoneum, which forms a complete envelope around it. According to Sappey, the peritoneum in the fetus reaches as high as the end of each round ligament, and forms an intra-inguinal canal known by the name of the canal of Nück, who was the first to give a description of the anatomy of this peritoneal prolongation in the year 1692.

In order to thoroughly understand the development of this canal, it is only necessary to say that the peritoneum adheres in its entire length to the round ligament, and that in the beginning of intra-uterine life the internal orifice of the inguinal canal is situated behind the external orifice. The peritoneum comes up near the latter, but later on the internal orifice is directed outwards, and little by little, as it becomes farther and farther away from the external opening, the round ligament with its peritoneal covering is drawn along with the internal orifice as it recedes, and thus is formed the canal of Nück. From the fourth to the sixth month it is very marked, and measures about six millimetres in length. Its evolution is exactly the same in both sexes, because the gubernaculum testis, which in the male goes through the same orifices, in order to reach the scrotum, is also drawn upwards and outwards, as the distance between the external and internal orifices of the inguinal canal becomes greater. Consequently the inguinal canal is occupied by the peritoneum when the testis enters, and traverses the canal when no obstruction is present. The gland at this time is about equal in size to the gubernaculum. In the female the canal surrounding the intra-inguinal portion of the round ligament no longer exists at birth, as it rapidly becomes atrophied. It often disappears at the eighth or even seventh month of intra-uterine life.

The question now arises, Can this peritoneal prolongation still be present after birth?

Duplay, in his thesis written in 1865, denies emphatically the existence of the canal of Nück, basing his assertion on personal researches carried out in 21 fetuses, who varied in age from four months to nine months, and in which he was unable to find this canal. However, Duplay's opinion has been since upheld by two of his pupils, Rabère in 1883 and Beurnier in 1885. The majority of anatomists are opposed to Duplay's opinion. Wharton has found a small canal,

the size of a goose-quill, measuring about a centimetre and a half in length and limited to the lower part of the inguinal canal, in young female cadavers. Out of 200 female cadavers Wrisberg found the canal of Nück in 19 of the subjects. Camper examined 14 newly born female children, and in 11 he was not able to detect any trace of the canal, while in the remaining three it was present; twice it was found on the left and once on the right side. The same writer in another series of 20 subjects found this canal closed up in 15, traces of it in three on the right side, while in two it was patent on the left. Sacchi found the canal in one out of three female fetuses that he examined.

Tillaux says that the canal of Nück is a prolongation of the peritoneum accompanying the round ligament, similar to the peritoneo-vaginal canal, which results from the descent of the testis into the scrotum. It is most often obliterated, but its remains may persist, which later on can become filled with fluid and thus form a cyst, constituting a hydrocele muliebri; and this is probably what happened in the writer's case, when we consider how late in life the tumor developed in his patient. Cruveilhier states in his work on anatomy that he had found this canal not infrequently in elderly women, and this statement is also upheld by the researches of Raouonede. The more recent anatomical researches of Richet, Féré, Senn, Virchow, Zuckerkandl and Hugo Sachs better demonstrate the possibility of the presence of the canal of Nück after birth. Out of 158 cadavers of subjects varying in age from birth up to three years, Féré found the peritoneal process accompanying the round ligament and perfectly patent on both sides in one, on the left in three, and on the right side only in one. The canal was incompletely obliterated on both sides in one subject; in nine the canal on the right, and in all on the left side were obliterated. Of these 17 subjects, eight were one month, two were over two months old, while the remaining seven had attained a certain age. Of 19 subjects varying in age from one to twelve months Zuckerkandl found the canal present on both sides in three.

Sachs examined 105 female infants, varying in age from birth up to one year, and found that 11 presented a canal of Nück on both sides; in 16 the canal was patent on the right and obliterated on the left side; while in nine, five were completely obliterated on the right and incompletely so on the left. In only one case did this writer find the canal perfectly permeable on the left. It may reasonably be concluded from what has been said that no doubt should any longer remain as to the possibility of the persistence of the canal of Nück in adult life; and thus having endeavored to prove this, we will now consider the pathology of the subject.

Serous cysts in the groin and labium of women were probably first mentioned by *Ætius* in the year 543 A. D., who gave the first description, after the writings of the midwife, *Aspasia*. *Ambroise Paré* reports that he operated on a hydrocele in a young girl of six years, in order to give issue to its contents. *Désault* reported in 1791 that he opened the tumor in a girl of twelve, giving issue to two or three ounces of serous fluid. The tumor had been present for some time; it was soft, transparent, the size of an egg, and situated on the round ligament. Many of the older writers — as *Lallement*, *Palleta*, *Lecat*, *Scarpa*

and Sacchi and others — attributed these cysts to the persistence of the canal of Nück after birth. Bends also has given a very good explanation; and Schroeder gives an excellent description of the affection in von Ziemssen's Encyclopedia, and divides it into two varieties, namely, an extra- and an intra-peritoneal form. Schroeder, Weber and Koppe admit the possibility of these cysts occurring in the interior of the round ligament. The latter attributes this origin to the hematic cysts which are sometimes met with, and may be properly termed hematocele of the round ligament. Ancelon, Morpain and Brochon consider these serous cysts to be like those developed in the dartol infundibulum, which was first described by John Hunter, and lately more completely by Broca. The dartol infundibulum is similar to the sustaining apparatus of the penis and scrotum, being entirely composed of elastic tissue, and has no relation to the dartos of the male.

The following paragraph is taken from Richet's work on topographical anatomy, from the edition 1866:

"A great rôle has been given by some to this so-called dartol sac, considering it as the seat of hydrocele in the female; but it suffices, in order to reject this manner of thinking to remark that, first, the dartos, which is not a sac, and still less a continuous membrane, is made up of elastic fibres, and can in no manner secrete a serous liquid; secondly, in the cavity covering these fibres only fat and the extremity of the round ligament are to be found; thirdly, the remains of Rosenmüller's body described by Giraldès in the middle of the region of the epididymis, and which are recorded as the origin of encysted hydrocele of the cord, which did not exist here; fourthly and lastly, no worthy pathological report has been given to uphold this opinion, which has not even an analogy, because, in the male, there is no such condition as hydrocele of the dartos."

Consequently it is impossible, as is stated by Vasseur, to attribute a hydrocele in a female to a dropsy of the dartol infundibulum, because this sac does not exist in a strict sense.

Richet gave three causes for hydrocele muliebris: first, hydrops of an old hernia sac; secondly, cysts of the vulvo-vaginal gland; thirdly, serous collections in the organs of the canal of Nück, or old sanguineous collections which had undergone a transformation.

The teachings of Velpeau can no longer be upheld, and the peculiar theory of Vidal (de Cassis) cannot be seriously considered. At the present it is probable that the majority of surgeons consider hydrocele muliebris as a serous fluid developing in the *débris* of the canal of Nück, and comparable to cysts of the cord in the male. Gaillard Thomas considers the affection as probably resulting from a hypersecretion of the serous membrane. If the abdominal opening of the canal remains patent, the fluid which collects may easily be forced upwards by pressure; but, if the orifice is closed, the liquid becomes encysted, as in the writer's case. Hennig, Hegar and Kaltenbach believe that cysts developing in the round ligament generally occur from some abnormal condition in the evolution of the canal of Nück, which is only obliterated at the internal opening of the inguinal canal. These cysts, only typical as in the writer's case, are elongated tumors, usually about the size of an egg, filling the inguinal canal and sometimes extending into the labium majorum of the corresponding side. At the posterior aspect of the tumor a whitish-colored band,

which is sometimes of a pale red hue is found, which is the round ligament. If the peritoneal canal is obliterated at all points, the cyst will have an hour-glass shape. Pozzi, Auvard and Tillaux also believe that these cysts originate in the remains of the canal of Nück. In the writer's case and the one reported by Richelot, the absence of any history of hernia, the isolation of the sac at the top of the labium majorum, the vascular elements in the walls, the interior formation which is in every way similar to the vagino-peritoneal canal of the male, the extreme narrowness of the connecting canal in Richelot's patient and its entire absence in the writer's case, clearly demonstrate that these were liquid collections developed in a *débris* of the canal of Nück.

In 1890 Wechselmann wrote a very important and complete paper on cysts of the canal of Nück, in which he clearly demonstrates that a certain number of cysts developing in the inguinal region in the female, originate in the remains of Nück's canal at its terminal end, its communication with the peritoneum having become more or less obliterated. Recently very conclusive facts have been reported by Berger, Terrillon and others, regarding congenital inguinal hernia in women, coexisting with hydrocele of the canal of Nück. It is certain that the remains of the latter, with the upper portion remaining patent, may cause a congenital hernia in the female in every way like the congenital hernia met with in the male, when the vagino-inguinal canal remains open.

Wechselmann reports three cases of these cysts, which were complicated with hernia, while Berger, Reclus, Rontier, Tuffier and Terrillon reported similar cases at the Surgical Society of Paris; and recently Cachau reports two others.

To sum up, it may be said that the many researches that have been carried out amply demonstrate that cysts may form in the remains of canal of Nück, and that they may be complicated with congenital hernia when the upper portion of the canal is not obliterated, the latter having the same pathogenesis as the cyst and developed simultaneously along with it.

The symptoms of hydrocele in the female are often quite distinct, and sufficiently characteristic to allow the making a diagnosis in many cases. The physical signs of these cystic collections are as follows: They are generally oval tumors varying in size from a cherry to that of a large egg; but this shape is not always the same, for they may be cylindrical or more or less pyriform, while the surface may present lobes such as were found in the writer's case. They may be situated in the interior of the inguinal canal or at the *upper and external* aspect of the labium majorum. This latter site is important for the diagnosis, because mucous cysts of the vulvo-vaginal gland are always situated in the *lower part* of the labium; in a number of cases the cyst was found to extend to the upper part of the labium. The diameter of the tumor is usually greater in the direction of the axis of the inguinal canal. In looking over the literature the writer found that these cysts occur more frequently on the left side.

The skin covering the cyst is normal, and can be moved easily over its surface. A kind of pedicle may sometimes be felt by palpation, as in the case reported by Manley, and is directed downwards into the inguinal canal. The consistency of these collections is often soft, but when they are moderately distended

fluctuation may be elicited. In the writer's case, however, the tumor was quite hard and elastic to the feel. Percussion will give complete dullness.

When the surgeon is in the presence of a true cyst of the canal of Nück, the tumor will be absolutely irreducible because the fluid is encysted. Sometimes, however, the tumor may be reduced *en masse* into the abdominal cavity, but it will immediately return to its former position as soon as pressure is removed. On the contrary, if the tumor is a congenital hydrocele, that is to say, a cyst developed in an unobliterated canal of Nück, it can be reduced by pressure or by simple dorsal decubitus. It is in these cases that the diagnosis is sometimes very difficult, and a very careful examination is necessary in order to decide whether we are in presence of a hernia or a simple cyst. However, the percussion, dullness, the ease of reduction (which is progressive and causes no gurgling sound when the sac slips into the abdominal cavity), the transparency of the tumor (which in some cases is quite distinct), are sufficiently good signs of hydrocele, if they are to be found.

There is no impulsion given to the tumor when the patient coughs, and in certain cases the cyst is more liable to retract. The contents of these cysts are usually clear and limpid, but may, however, present the characteristics of a hydro-hematocoele, or even a true hematocoele.

Generally speaking, the functional signs are of little importance, as the patients rarely suffer from their tumor, even when it has attained a considerable size. The evolution is usually very slow, and the surgeon will rarely see the patient when the tumor is still small. It is only after it has reached a certain size, producing considerable inconvenience, that the patient will ask for an operation.

A condition of affairs that has been observed in several cases is acute inflammation of the cyst, which may produce accidents similar to those occurring in strangulated hernia, and some surgeons have operated on such cases supposing they were in presence of a hernia, and have been much astonished when they cut down and found a simple cyst.²

The diagnosis of this affection would appear to be quite easy; but in reality it is not so, and many mistakes have been mentioned by various authors. The principal affections which are to be taken into consideration are cysts of the labium, hernia, hernia of the ovary, varicose veins of the round ligament, lipoma of the labium, dermoid cysts of the skin, fibroma or fibromyoma of the round ligament, as well as sarcoma, although the latter affection is extremely infrequent in this region.

Regarding the treatment, the writer has little to say. It naturally consists in an extirpation of the cyst and ligation of its pedicle. This, of course, applies to the true form of cysts of the canal of Nück, in which no communication exists between them and the peritoneal cavity.

Puncture, and removing the fluid, followed by an irritating injection, would naturally be bad practice, and is only mentioned here to be condemned.

GOLD FOIL IN CEREBRAL SURGERY.

BY H. H. A. BEACH, M.D.

It is now nearly seven years since I published¹ an account of an operation undertaken June 11, 1889, at the Massachusetts General Hospital to remove the source of irritation in a case of epilepsy. The patient was a young girl and the disease had existed for eight years, following a compound comminuted fracture of the skull at the parietal eminence of the left side. The steady increase of convulsions and the progressive mental deterioration made almost any condition preferable to the future toward which she was drifting. The operation was determined upon without much hope of its affording permanent relief; and consisted of a removal of the soft parts covering the fractured area, and a careful dissection of the dense cicatrix from the bone until the brain was liberated from its anchorage. The removal of fragments at the time of the original injury made trephining unnecessary. The protruding cicatricial tissue was dissected from the brain until the latter seemed to the touch, of normal consistence. The lacerated dura was included in the cicatrix. In the course of this dissection a projecting spicula of bone which had grown from the fractured border of the skull toward the brain was removed, also a small cyst, containing a clear fluid. The wound was closed with sutures, and recovery was uneventful and complete.

A report of the case was delayed for ten months lest the convulsions should recur. The causes of irritation presented by the wound, were the spicula of bone, the cyst, or the rigid attachment of brain and bone by cicatrix, singly or jointly. The latter limited the accommodation of the brain to head movements or skull concussions and favored the direct transmission of any force applied to the skull toward the point of suspension.

In anticipation of a recurrence of convulsions through a new adhesion to the bone I made the following provision in the report of the case: "Should it become necessary to repeat the operation described, it has occurred to me that a sheet of very thin aseptic gold foil might be left between the surface of the brain and the external flap—its ductility should theoretically adapt it easily to any pressure. Being non-corrosive and easily made aseptic, it offers the best and least irritating barrier to adhesion, that through traction might cause irritation of the brain. It furnishes a solution for a possible difficulty, and no objection to its use occurs to me."

For fifteen months the patient was free from convulsions. Then while stepping down from a wagon her dress caught upon the iron step and she was thrown violently to the ground, her head striking upon the site of the old injury and operation. Convulsions began at once, and continued with varying frequency each day until she entered the hospital again for treatment in the spring of 1892.

Bromides were used but with a negative result. The old wound was again opened; and, as before, a tough cicatrix was found firmly uniting the brain and bone. A careful dissection separated them and removed the cicatricial tissue from the brain as at the first operation. The finger could then be swept around and within the entire circumference of the skull opening. To prevent re-adhesion a plate of

² Mr. Wm. Thomson (Dublin Journal of Medical Science, December, 1896) relates a case of supposed strangulated labial hernia. The patient was admitted, suffering from symptoms which suddenly came on. There was a lump in the groin which had suddenly become larger, painful and tense; then followed vomiting and prostration. The tumor extended from the external abdominal ring into the left labium. Incision showed that the tumor was a cyst of the canal of Nück.

¹ Boston Medical and Surgical Journal, April 3 and 10, 1890.

sterilized gold foil (No. 60, Dental) enough larger than the opening to be retained in place against its bony edge by the pressure of the brain from beneath, was inserted, constituting a metallic dura-mater. The skin flap was turned back to its place covering the foil, and sutured. Rapid healing followed, with no evidence of local or constitutional irritation. The patient was exhibited at the annual meeting of the American Surgical Association, June 1, 1892.

After the second operation the convulsions occurred frequently for the following year, but with diminished intensity and much irregularity. They were more frequent at the menstrual period and after over-indulgence in eating. By the following October a favorable change had been noted by her family, which continued to June, 1894 (two years after the second operation), when the seizures had become light and were with few exceptions limited to the menstrual periods. She had become interested in household duties, and attended to them in a manner most satisfactory to her family. One year later she is reported as better in every way. Has had only one slight seizure since January, and in that time performed the duties of nurse for two members of her family in addition to the household work for three others. Her general intelligence, memory and capacity have deeply impressed those most interested in her and she has become less irritable and headstrong.

This general improvement has continued to the present time, and in other directions. She had a number of convulsions for one day in March, 1896, followed by an hysterical condition for a few days; then she is reported as well as usual for nine weeks, when she had a light seizure. Again, in August, she had three in the night (the last reported). Both of the later attacks were associated with the menstrual period.

Time alone can settle the permanency of the relief in this case the report of which has been delayed five years lest the apparent gain should be reversed. If the rigid adhesion of the brain to the bone was the primary source of the convulsions, it is reasonable to believe that the prevention of such adhesions should operate toward their relief. The adoption of a gold plate for that purpose was the result of necessity, for nothing else promised so much. While it is yet impossible to determine the value of the principle, owing to the limited number of operations where it has been used, no unfavorable reports from its employment have been reported. The recorded cases are encouraging in the direction of a procedure that, without delaying union or adding to the common risks, protects the brain from injury and protrusion during and after healing, and provides against such well-recognized sources of brain irritation as the adhesions that may follow any case of compound skull-fracture or its equivalent by operation.

Since this patient was first exhibited to the profession in 1892, the subject has had the kind interest of Drs. Weir, Abbé and Gerster of New York, Keen of Philadelphia, Roswell Park of Buffalo, Tiffany of Baltimore, and Oliver² of Cincinnati, who had the opportunity of examining a case post-mortem. He found upon examination of the wound that the gold plate was in position, and that it had accomplished the purpose for which it was inserted, the prevention of adhesions. Estes, of Bethlehem, Pa., makes a report of

three most interesting and successful cases where the foil has been used to replace the dura and prevent the escape of brain tissue.³ Sachs and Gerster, in their analysis of 19 cases, state that "the only method known to us at the present time, to avoid the formation of these scars is the introduction of some pliable metal plate between the dura and the skull."⁴

Medical Progress.

REPORT ON PROGRESS IN THORACIC DISEASES.

BY GEORGE G. SEARS, M.D.

SHOULD CONSUMPTION BE TREATED IN A GENERAL HOSPITAL?¹

APROPOS of three cases of pneumonia treated in his wards, each of whom ultimately died of phthisis, Jaccoud raises the question whether consumption ought to be treated in the wards of a general hospital. In each instance the pneumonia was the result of an injury, and occurred in previously healthy persons without tubercular taint. Although carefully looked for, the tubercle bacillus was not found. The disease ran a favorable course; but shortly after recovery all three patients showed signs of phthisis, to which they finally succumbed. At the autopsy there was nothing to show that the tubercular infection was not of recent date; yet the question must remain unsettled as to whether the bacilli were dormant in the tissues of the patient during health and were started into activity during the progress of the pneumonia, or whether these cases were infected by other phthisical patients in the same ward. In the absence of proof the latter should not be affirmed, as he is convinced that non-phthisical patients can be protected by proper hygienic regulations, which are also essential for the safety of the consumptives, who unquestionably suffer to a considerable extent from the presence of other organisms in the wards. The most important hygienic element is the suppression of dust.

THE PRODUCTION OF PLEURAL EFFUSION.²

Leathes and Starling give details of experiments to determine the cause of the pouring out of fluid into the pleural cavities, and say that if it is permissible to apply these data directly to the explanation of clinical phenomena they may formulate the following conclusions:

(1) So long as the vessels are healthy no change in the pressure of the blood in the capillaries supplying the pleura is able to bring about pleural effusion.

(2) In the hydrothorax of heart disease we have probably the concomitant working of several factors, that is, the raised capillary pressure, and in many cases a certain amount of hydremic plethora. These, however, are acting in the capillaries which are suffering from malnutrition, and are therefore in a subinflammatory condition. There is at the same time an impediment to absorption in the obstruction to the flow through the thoracic ducts caused by the venous engorgement.

¹ Bull. de l'Acad. de Méd., February 11, 1896.

² Journal of Pathology, 1896, iv, p. 175.

³ Loc. cit., April 1, 1896.

⁴ American Journal of Medical Sciences, October, 1896.

² Journal American Medical Association, May 30, 1896.

(3) In the exudation of pleurisy the chief factor is an increased permeability of the walls in the capillaries of the subpleural and mediastinal tissues. The increased exudation hereby produced makes its way in the direction of least resistance, namely, into the pleura. The clots formed in the inflammatory exudation adhere to the pleural wall, and tend to check absorption, which is also probably hindered by the pressure of the peripleural exudation in the subpleural lymphatics. In every case, therefore, where effusion into the pleura is produced, diminished absorption is associated with the increased exudation of fluid from the blood-vessels.

CAUSATION OF SUDDEN DEATH IN EMPYEMA.*

Hutton divides the cases of sudden death in empyema into three classes, according as it begins from the heart, from the lungs or from the brain. Of these the first appears to be the most common, but has never been satisfactorily explained. With a view of determining the exact condition within the thorax in the presence of a pleural effusion he made a series of experiments on rabbits by injecting the pleural cavities with fluid. He concludes from them that there is danger of fatal syncope with an effusion in either pleural sac, the causes of which are the displacement of the heart and its having to do greater work than normal and under increased difficulties. In left-sided cases the base of the heart rolls around over the inferior vena cava and narrows its lumen, while at the same time the vessel is somewhat stretched and twisted. Any slight movement occurring when these vessels are partially obstructed may cause an increase of the displacement and produce fatal syncope.

In right-sided cases the effusion will press down the diaphragm and stretch the inferior cava. At the same time the effusion will press almost directly on the thin walls of this vessel and interfere with the flow of blood through it. This would be sufficient to account for the edema sometimes seen in right-sided cases.

Of the second group of cases, where death begins at the lungs, some are due to emboli of the pulmonary vessels, others to a rupture of the empyema into a large bronchus producing fatal asphyxia, or to the rupture of a blood-vessel, the blood being drawn into the lungs. Other cases have been described where a pneumo-thorax developed in one side, the other lung being collapsed by a pleural effusion. Cerebral emboli are probably a more common cause than is generally suspected, the most favorable conditions for their formation being found in many cases of empyema.

Of the third group many deaths have occurred while the pleural cavity was being washed out after operation, in some of which hemiplegic attacks and general convulsions have occurred. It has been customary to attribute these accidents to the amount of liquid used and its irritating properties, but probably neither of these factors has much to do with the disastrous results which have followed, although the washing out of an empyema cavity may cause the dislodgment of a thrombus in the pulmonary vessels, or the injection of an irritant lotion cause fatal shock or general convulsions. Among other causes not included in any of these groups, death under chloroform at the time of operation is the most important, while sudden death from hemorrhage may occur.

LATENT AND TRANSIENT PERICARDIAL EFFUSION.⁴

Ewart reports three cases of latent pericardial effusion, which were associated in one instance with nephritis, in another with valvular disease, and in the third with acute rheumatism, where he had an opportunity of following the process from beginning to end. They were similar to the "quiet pleurisy" described by Clifford Allbutt, but he does not yet feel that he possesses a sufficient series of clinical cases to construct a group of quiet pericarditic effusions absolutely analogous to them.

He summarizes his paper as follows:

(1) Effusions may occur in the pericardium independently of acute pericarditis under the influence of rheumatism, of cardiac affections, of Bright's disease, etc.

(2) If of moderate size they may be capable of rapid reabsorption; and in that case, not attracting attention either by the painful symptoms of pericarditis or by the pressure symptoms of fluid, they may often run their course unobserved.

(3) As in the case of analogous pleural effusions they may be dependent on a subacute inflammatory process. More often they are probably passive or mechanically induced.

(4) Rest and diet and the administration of cathartics, of diaphoretics and diuretics are the only treatment needed in the average case. In severe cases, which are usually those of advanced kidney disease, the effusion as it steadily increases becomes obvious and paracentesis may become necessary.

(5) The most important practical conclusion is that our physical examination should be accurate and searching, and that in all cases of enlarged precordial dulness the simple tests for the presence of pericardial fluid should be thoroughly applied. Of these the most important is the alteration of the convexity of the dulness due to the right auricle into a straight line passing outwards and downwards and forming an angle with the hepatic line of absolute dulness.

In a later paper on "The Dorsal Test for Pericardial Effusion,"⁵ the same writer calls attention to the importance in diagnosis of the invariable appearance of an area of absolute dulness quadrilateral in shape and localized to the interval between the tenth and twelfth ribs close to the spine. This cannot be due from its position either to the fluid within the sac or to the heart itself, but probably results from the following influences: a slight downward displacement of the compressed base of the lung, a similar displacement of the anterior portion of the left hepatic lobe under the weight of the pericardial fluid without any marked depression of its posterior portion, and a corresponding depression of the stomach with or without slight displacement to the left. Such an area of dulness occurs normally in children and pathologically in some cases of extreme wasting in adults, but this does not detract from the practical value of the test, since in both instances when pericardial effusion occurs, its detection by the usual methods of percussion is favored by the smallness of the chest and the thinness of its walls; whilst its absence can be readily made out. Difficulties in diagnosis more commonly arise in non-emaciated adults, but among the many healthy adults whom he has examined for this sign

* Edinburgh Hospital Reports, vol. iv, p. 240.

⁴ Lancet, November 21, 1896.

⁵ Loc. cit., January 23, 1897.

he has failed to find it in a single instance, and he therefore regards it as always suggesting a strong suspicion of pericardial effusion. In cardiac enlargement the dulness in question might be expected, but he has failed to find it in any of the adult cases which he has examined. In young subjects this is a source of fallacy carefully to be borne in mind.

PUNCTURE AND INCISION OF THE PERICARDIUM.⁶

After giving a brief historical review of the subject, Delorme and Mignon discuss the differential diagnosis of pericardial effusion, its clinical history, the indications for operation and its technique. They recommend that aspiration be first performed, since if the fluid is serous or sero-sanguinolent no more radical measures may be required, but if it is feared that adhesions exist between the pericardium and the anterior wall of the heart, it is better to perform incision in the first instance than to run the risk of plunging the needle into an organ the wounding of which may prove fatal to the patient. If pus is found, free drainage should be immediately obtained. If the fluid, however, rapidly re-accumulates and aspiration has to be repeated several times, the indication seems clear that the simple operation is not sufficient and that the more radical method of treatment by free incision is required. No danger from a rapid evacuation of the fluid is to be apprehended.

The authors recommend a somewhat elaborate technique for the performance of paracentesis of the pericardium. An incision is to be made through the skin, starting from a finger's breadth below the lower border of the seventh costal cartilage and continuing upwards across the sixth and fifth intercostal spaces. The needle is then slowly inserted close to the left border of the sternum, preferably in the sixth interspace if it be wide enough to admit the needle, otherwise in the fifth or very exceptionally in the fourth. After the point of the needle has entered to the level of the posterior surface of the sternum, the handle is much depressed, and the point then carried upwards parallel to the sternum for about half an inch. The handle is then raised and the needle is pushed onward until fluid appears. After evacuation the incision is sutured. The internal mammary artery is thus avoided, and the danger of wounding the left pleura or the heart minimized. It is very important to avoid wounding the pleura, although probably little harm would result if the effusion was serous, but if bloody or purulent the effect might be disastrous. It is not always possible to avoid it even by the method advised, as they found that in 32 cadavers, the pleura was wounded twelve times when puncture was made in the fifth space and six times in the sixth. When the third or fourth space was selected it was pierced in nearly every instance. They found but one case where death was directly due to puncture, that reported by Callender. The trocar was plunged into the fourth left space near the sternum and two ounces of blood withdrawn; five minutes later the patient succumbed to a pericardial hemorrhage. Autopsy showed that the ventricle had been perforated in the middle of its anterior surface. In several other instances the heart was wounded, but not deeply enough to give rise to hemorrhage or to a fatal syncope. For the operative procedure recommended in incision of the pericardium reference must be made to the original article.

Of 100 cases which they have collected from literature 82 were cases of simple aspiration and 18 of incision. Of the former 54 died, about 65 per cent.; of the latter, seven, about 38 per cent. These figures are, however, absolutely worthless in estimating the value of either operation as most of the cases were already *in extremis* when it was done. Better results are to be expected when it is resorted to earlier, provided the pathological process which is present permits cure, and even then it may have considerable value as a palliative measure. The successes obtained by the surgeons in tubercular peritonitis give ground for hope that even if cure is not obtained life may be prolonged by a similar procedure in cases of tubercular pericarditis.

A CASE OF CALCAREOUS DEGENERATION OF THE HEART AND ARTERIES.⁷

Bramwell reports what he considers the most remarkable case which has come under his notice during a practice of twenty-seven years.

The patient was a man, twenty-five years old, without suspicion of syphilitic taint. When eleven years old he suffered from what, in the light of later events, was probably a pyelo-nephritis. He apparently fully recovered, and eighteen months before his last illness went to Winnipeg, where he endured great hardship and exposure from which he completely broke down. He never fully regained his strength, but had recently been able to do hard physical work without sense of weakness or shortness of breath.

Three weeks before Bramwell's first visit he strained his back lifting a heavy piece of machinery and had to go to bed. When seen he was extremely feeble, much emaciated and markedly anemic. The skin of the abdomen was very dark, resembling the color of a case of advanced Addison's disease. The areolæ of the nipples were also dark. The heart's action was exceedingly feeble, the impulse imperceptible, the sounds almost inaudible. A soft blowing murmur was present both in the pulmonary and mitral areas. The pulse was small and very weak; but at this time no special abnormality of the radial vessels was noticed. The urine was very pale, and measured from three to three and a half pints a day; its specific gravity was 1.010. It contained a trace of albumin, but no casts were found. On the anterior and posterior folds of each axilla, the flexor aspects of both elbows, the upper part of each thigh, over the superior anterior processes of the iliac bones and over the adjacent parts of the inguinal folds, the posterior fold of each buttock, and in each popliteal space were hard, brawny swellings; while the skin of the affected region was a purple-brown color. The condition of the skin and subcutaneous tissues over the swellings more closely resembled a cancerous or sarcomatous infiltration than in any other condition which has come under his notice. Many hard, small nodules, like small shot, were situated in the margins of the swellings and in the adjacent skin. In the centre the individual nodules seemed to have run together so as to form hard continuous masses. The swellings were hard and dense, and in places gave one the impression of being infiltrated with calcareous matter or with bone. They were not painful, but somewhat tender when pressed upon.

At a later visit both radial arteries were absolutely rigid and pulseless, and could be traced from the wrists

⁶ Rev. de Chir., October and December, 1895, and January, 1896.

⁷ Edinburgh Hospital Reports, vol. iv, p. 175.

to the elbows. The femoral and politeal arteries were also rigid and almost pulseless.

At the autopsy the heart was found to be an extraordinarily good example of calcareous degeneration, which affected not only the interstitial tissue but the muscular fibres as well, while the trabaculæ carniæ and papillary muscles of the left ventricle were almost entirely calcified. All the arteries except the aorta, the carotids and those of the brain were more or less affected—the iliac, femoral, popliteal, tibial and radial arteries being converted into rigid tubes. The subcutaneous swellings were due to calcareous material which had been infiltrated around the blood-vessels, and in that way had produced inflammatory changes in the connective tissue. The right kidney was entirely destroyed, evidently as a result of old disease. The left was in a condition of very advanced cirrhosis. Many minute calcareous deposits were present in the cortex; the arteries in the pyramidal portion were calcareous.

Not the least interesting point in the case is the apparent rapidity with which such marked degenerative changes took place, as it is hardly possible to believe that with such a condition of the heart and arteries that the patient could have been equal to the prolonged and violent muscular efforts which his work required three months before his death, while his own statement and that of the attending physician are positive that the subcutaneous swellings were not present more than six weeks before.

SYPHILITIC DISEASE OF THE HEART WALL.⁸

Phillips gives a brief summary of 25 fatal cases of disease of the heart wall, which was undoubtedly of syphilitic origin, and discusses at length the symptomatology and pathology of the affection. He draws the following conclusions:

(1) Syphilis may produce gummata or general fibroid change.

(2) Gummata in the left ventricle, except of very small size, are dangerous to life, and when near the apex of the left ventricle may cause sudden death.

(3) Gummata in the left ventricle may be suspected if in an individual with syphilitic antecedents there occur signs of derangement of the action of the left ventricle with symptoms of defective or embarrassed action, especially angina pectoris, tachycardia, syncope or epileptiform attacks, or in the right ventricle when dyspnea otherwise unaccountable occurs.

(4) Extreme feebleness of the heart, without dilatation, gradually increasing in young or middle-aged persons who have had syphilis suggests syphilitic disease of the left side of the heart, and long-standing dyspnea may point to similar disease on the right side of the heart.

(5) Dilatation of either side of the heart in syphilitic persons may result from syphilitic fibrosis.

(6) Hypertrophy of the heart without ascertainable cause and without corresponding increase in strength of heart suggests syphilis.

(7) Aneurism of the heart wall may result from local syphilitic lesions and may be fatal with or without rupturing.

(8) It is probable that gummata and fibroid disease in the early stages may be relieved or cured by the usual specific treatment, and there is every reason to believe that syphilitic lesions of the heart wall are not

less amenable to treatment in the early stages than syphilitic lesions elsewhere, though no cure can be expected when advanced tissue changes are already produced.

(9) Syphilitic heart lesion is much more common than is generally recognized, but the importance of recognizing it is greater because it affects persons at an earlier age than the usual degenerative heart conditions, and may insidiously advance till it causes sudden death in persons in the prime of life and of apparent health.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

J. G. MUMFORD, M.D., SECRETARY.

REGULAR Meeting, Monday, December 14, 1896, DR. C. J. BLAKE in the chair.

DR. F. I. KNIGHT, read a paper entitled

THE TREATMENT OF BRONCHIAL ASTHMA.¹

DR. V. Y. BOWDITCH: Dr. Knight has covered the ground so thoroughly there is little left for me to add. The more I see of these cases the more it seems to me that they must be dependent upon some neurosis, that is to say, reflex action from disease of other portions of the body whether from the nose, heart, stomach, lungs or kidneys. As far as medical treatment is concerned, the iodide of potash and syrup of hydriodic acid sometimes in combination with arsenic have met with more success in my hands than other drugs; and here it may be well to state that an examination has been made of a certain remedy used by a famous institute in a neighboring State, from the use of which some persons certainly have got relief from asthmatic troubles. The chief ingredients of the medicine they used were found to be iodide of potash and arsenic, but how much the element of faith comes in as a factor in the relief it is impossible to say.

Dr. Knight has spoken of one method of treatment, namely, inhalation of rarefied air. This is doubtless often a most beneficial method of treatment, the chief difficulty of using it, however, being the usual inaccessibility of the instruments for applying it during the attacks.

Six or eight years ago, when much interest was shown in the so-called pneumatic cabinet, I had opportunities of testing its use in cases of asthma. I recall one young girl, a severe sufferer at times with acute bronchitis accompanied by asthma. By means of this instrument the alternate use of compressed and rarefied air (the so-called "pneumatic differentiation") gave her great relief in her attacks. The neurotic element must always be considered in such cases of course; but the patient was of calm temperament, and the relief obtained in her case was doubtless due to the mechanical effect of forcing open (as it were) the contracted bronchioles in inspiration and of assisting expiration by the use of pneumatic differentiation. The danger of over-distention of the air-cells in such cases, which are prone to emphysema, must be kept in mind, but if judiciously used, no harm can come from the treatment.

For the severe and sudden attacks of spasmodic

⁸ *Lancet*, January 23, 1897.

¹ See page 273 of the Journal.

asthma doubtless the subcutaneous use of morphine gives greater relief in the majority of cases than anything else; but, as Dr. Knight has said, the danger of forming the morphine habit must be faced.

As to climatic treatment it is impossible to say absolutely to a patient, "Go to such and such a place and you will get relief." In advising patients I usually say all such changes have to be experimental at the outset. There is scarcely any disease in which such diametrically opposite results will be obtained in cases resembling each other. I have known some cases to become much worse in some of the New Hampshire resorts which have a just reputation for the relief of many, and residence at a lower level will often give such cases more relief. We may say, as a rule, however, that the higher altitudes offer relief to the majority of asthmatic patients if the heart is not weak.

It is not an uncommon experience to have patients improve vastly by a removal from the suburbs to the heart of the city. I have two patients in mind now, one a resident of Jamaica Plain, another of Milton, both of whom have lived perfectly comfortably since removing their place of abode to the city.

DR. PUTNAM: I have listened with great interest to the report of Dr. Knight's experience in this subject; and perhaps the most striking thing I can say is that these cases, although considered to be due to a disturbed condition of the nervous system, rarely come to the notice of neurologists. At the hospital, where we have an out-patient clinic of 2,000 nervous cases a year, we almost never have a case of asthma, and those I have seen in private practice have been relatively few. They go very properly to those who have to deal more especially with the lungs. As far as my experience has gone, I can only corroborate what Dr. Knight has said, that the same patient sometimes does well in a climate in which at another time he does badly. When we are studying the general cause of the disease the temptation is very strong to feel that the chemistry of nutrition is sometimes very much at fault, as it is supposed to be in epilepsy and exophthalmic goitre and other periodical neuroses; but the more closely the question is investigated the more difficult to fasten on any special ingredient in the blood or any special fault of nutrition which would account for these states. I have been interested in following the uric-acid theories and observations, and am fairly familiar with those of Haig, who has been the prophet of the uric-acid hypothesis; but I think it is very difficult indeed to verify his statements, and those that seem to come the closest to his work regard it with the most suspicion. That there is something for which that stands for the general expression there seems to be no doubt, but that it is uric acid may be called in question. In the last few years Dr. Rachford, of Cincinnati, has been bringing forward paraxanthine as a cause of some of the symptoms that Haig attributes to uric acid. As time goes on I have no doubt we shall find other poisons. The urine after an attack of epilepsy, and sometimes before an attack, occasionally contains substances very poisonous to animals when injected. Nobody knows exactly what they are. I have been especially studying the epileptic question; and I think it is probable that the disorder of nutrition which causes the epileptic attack is a very subtle one, and I fancy the same is true of asthma.

With regard to the use of arsenic and iodide of

potash, I think the question of dose is interesting; and with regard to their mode of action, why it is some patients require such large doses and others are benefited by small ones, it would seem that the action upon the nervous system must have something to do with solving the riddle. One patient I treated—a gentleman, a lifelong sufferer from asthma—had at the time I treated him, arsenic in his urine, and was suffering from a severe form of multiple neuritis, by which he had been very much prostrated, and it was attributed to the arsenic. I gave him iodide of potash. He did not get better, and put himself in the hands of the persons to whom Dr. Bowditch has alluded, and they gave him a mixture of both of these ingredients, and he promptly got well.

DR. FARLOW: I wish merely to emphasize one point. The reader has spoken of the local treatment of certain parts of the upper air-passages. I believe many of our older patients could have been helped if they had been started in the right way when young. If children and young persons, frequent sufferers from tonsillitis, bronchitis or other diseases of the air-passages, could have their noses, post-nasal spaces and fauces freed from all obstruction and the sensitive areas removed, they would arrive at adult life with much healthier and less sensitive bronchial tubes. I think we should try, as early as possible, to remedy the conditions whose removal are not so likely to cause a cessation of the asthma when they have existed for many years.

There is a form of asthma in young, nervous women where systematic exercise is of great benefit. They wear thick clothes and thin shoes and take almost no exercise, as a general thing. If they can be prevailed upon to go to the gymnasium and get their muscles and skin in a healthy condition, they can often overcome the tendency to the secretion of thin mucus from the nose which is soon followed by an attack of asthma on going to bed. They become able to exercise without the liability to take cold.

DR. COBB: I have been very much interested in this paper for more than one reason. Among other things I think it has been instructive to note in what cases of nasal obstruction one can expect relief from asthma, and it seems to me that those which have a hyperesthetic mucous membrane of the nose were much more easily relieved by nasal operation than other classes of cases. One case especially, which I operated on for large nasal spur, which had this hyperesthetic condition in a very marked way and had constant paroxysms of asthma, was relieved for three years; so much so that when he applied to me three years afterward for an excuse from school drilling, and I told him if he could honestly say that he had any asthma which unfitted him from work I would give him the certificate, he was unable to say it. Five years after operation he had one attack; but during all that time he was practically free from asthma and without any treatment except on the spur. On the other hand, some polypi cases have had more asthma after their polypi were removed than while the polypi were still there; and that has puzzled me, and I should like to ask Dr. Knight if he has had any such experience. I think possibly it was due to the irritation of the mucous membrane of the nose by the removal of the polypi or by some underlying cause of that kind. I have noticed it in two or three cases.

DR. CLARK: I have had a number of cases in which

a diseased condition of the nose has evidently been the cause of asthma, and I should like to ask Dr. Knight if he has any statistics as to the proportion of cases which start from diseases of the nose or throat.

DR. J. MORSE: I should like to ask Dr. Knight more about the climatic treatment of asthma, whether there are any places about Boston, like Lexington, which are favorable, and whether there are any places abroad especially fitted.

DR. KNIGHT: As to Dr. Farlow's suggestion of remedies, the *grindelia robusta* I have used a good many times with relief, and a good many others I might mention; but on the whole they are inferior to those to which I gave prominence. In regard to cocaine, while I might use it if a patient was suffering in my office, without his knowing what I was doing, I would not give a patient a prescription for cocaine because I have seen such deplorable results from it. I do not know how many patients I have seen who have got that habit or that combined with morphine. It is, I think, one of the worst drugs to allow a patient to use for himself. Dr. Farlow, I know, did not mean that. I have done just as he suggests. It is so dangerous I do not use it myself now. It has a very bad effect on the mucous membrane ultimately if used long. In regard to the proportion of cases of asthma due to nasal disease, statistics on that are very unreliable. It is almost impossible to get a correct table. I suppose if cases reported from all sources were gathered together and some statistics made, they might be of service.

In regard to what class of nasal cases are relieved by operation, I have seen a good many cases which are relieved for a short time by removal of polypi, but who begin to have attacks soon afterwards, a few weeks or at most a few months. I have never seen a case immediately made worse by the removal of an obstruction, as Dr. Cobb suggests; but I should suppose that his explanation might be the correct one. The reason that removal of nasal polypi or the removal of any other nasal disease does not effect a cure in all cases is that some other factor, as I suggested, is left. One patient may have asthma because he has got two or three contributing conditions, and the removal of one will not cure. Many of those patients have a hyperesthetic condition of the nervous system that causes them to go into an attack on slight irritation—some remote irritation which it will take long to discover, if discovered at all.

In regard to special climates, I am not prepared to answer that. As Dr. Bowditch suggests, the high altitudes seem to relieve perhaps the larger proportion of cases, but there the purity of the air comes in. A climate like Colorado is freer from irritants than lower altitudes, but many patients suffer in high altitudes. In regard to patients nearer home, I do not know of any difference; one patient will have it at home, others at the shore. On the whole, more patients are relieved by going to the city from the country. In a city as large as London it is common to have patients suffering tremendously come to consult, and find their symptoms all gone when they get to the consulting office. I remember in Berlin one man who used to suffer tremendously from asthma, and if he could get out over the nasty, foul-smelling river, and take a few whiffs of the stinking atmosphere the rest of us could hardly tolerate, he would be completely relieved.

DR. J. W. ELLIOT read a paper on

SOME CASES OF GALL-STONE SURGERY.²

DR. ARTHUR T. CABOT said that he was sorry to have been detained and unable to hear the paper, but that he would like to say a few words on certain points in the surgery of the gall-bladder. In the first place, he thought it extremely important that we should recognize the fact that in gall-bladder surgery, as in most of our abdominal work, an early operation is pretty certainly a successful one, whereas a late operation may often be fatal. He had the misfortune to have several cases (two or possibly three) die after the operation of opening the ducts and removing stones from them. In every case the patient came to operation in a state of extreme icterus and great exhaustion and emaciation from the long suffering and stoppage of the duct.

In regard to total extirpation of the gall-bladder, he said that until this year he had had no case in which a second operation had been required where he had removed stones and left the gall-bladder to close up. He had, however, recently had such a case, in which a recurrence of gall-stones occurred, and which, as far as it goes, is rather an argument in favor of total extirpation when that can be readily accomplished.

Speaking of the matter of diagnosis, Dr. Cabot said that he had seen several cases in which the patients had been thought to have malaria on account of the regularity of the chills accompanying the gall-bladder inflammation. This is not so surprising a mistake as it might appear, for the pain about the gall-bladder is sometimes trifling, while the chill appears as the important symptom, and if the chills are coming frequently, with a little stretch of the imagination, a certain amount of periodicity may be made out.

He spoke of three cases of difficult diagnosis which had occurred to him within the year, in two of which the disease had proved to be cancer of the papilla, while in the last case the symptoms were those of a general peritonitis and pointed to the region of the appendix as the starting-point. On account of the existence of a slight amount of bile in the urine, the incision was made high up for an appendix operation in order that both regions might be explored at once. The gall-bladder was found distended and very much congested, so that it had a deep purplish-red color, and on incision it was found to contain much purulent serum and a single large stone.

In regard to the treatment of cases of stone in the common duct, he thought that where the patient's strength was sufficient it was wise to incise the duct and remove the stone. In one case, however, in which he operated upon a man very much emaciated, who was very feeble at the time, it was felt that the patient's strength was not sufficient to stand a prolonged operation, and on that account the stone, which was found wedged in the common duct, was needled in the manner practised by Mr. Thornton. After this it crumbled under the pressure of the finger and the patient made a good, though slow, recovery. The icterus persisted for considerable time, leading to the belief that the calcareous matter had clogged the duct for some time after it had been crushed. Since the icterus has disappeared, however, the patient has enjoyed perfect health.

He thought that this operation of crushing the stone in the duct was one which perhaps ought to be prac-

² See page 275 of the Journal.

tised more than it usually is, and felt that one of his other cases, that died after an operation for the removal of the stone, might have survived needling and crushing in the manner just described.

He said he had not practised suture of the duct, partly because of the difficulty, which is especially great if the patient is stout, and that he had not made special effort in this direction because the teaching we get from other ducts in the body shows that the healing of a longitudinal cut in a canal usually takes place with extreme rapidity and very satisfactorily. In the urethra we see that fact constantly illustrated. In external urethrotomy we never sew the urethra and it always heals satisfactorily. Once in the removal of a stone from the ureter he had followed the same plan—incised the ureter longitudinally, and the canal closed perfectly. Of course, if the cystic or other duct is torn across so that the ends have any tendency to draw apart, stitching might be of the greatest value to keep the ends together, but it seemed to him that in a longitudinal cut for the removal of a calculus, drainage with gauze was usually sufficient. He had had a number of cases which ran a fortunate course by that procedure.

DR. BEACH: I would like to add my congratulations to Dr. Elliot for the brilliant success of his operation, and speak of one point, and that is, the relief which is given patients in a good many instances by the separation of adhesions, dividing them in front, posteriorly or wherever they may be, tying the gall-bladder to the anterior abdominal wall, to the liver or intestines. In two instances where the symptoms were extreme and suggested an ulcerated gall-bladder with discharge of the gall-stone, I have observed much relief. In both of them the gall-bladder was opened and drained. In one there was no possibility of making any connection between the gall-bladder and the intestine, the common duct having been searched for in vain. It was the case that Dr. Richardson speaks of, and upon which he had already done the ideal operation. When the patient re-entered the hospital she had a recurrence of jaundice with extreme pain and the gall-bladder was much distended. Upon its being opened no stones were found, though the pain was that of an impacted stone. The gall-bladder was therefore drained giving great relief. There was no possibility of closing the gall-bladder without making some connection between that and the intestines. As I had recently seen a case of abscess of the liver due to septic infection through the gall-duct from the intestine, I deferred making any connection between the gall-bladder and the intestine. Meantime she was draining and the question of there being any malignant growth deeply seated at the point where the adhesions were greatest was being settled by time. I told my assistant, Dr. Pegram, one day, that the case would be a most favorable one for making observations upon the action of medicine on the liver and asked him to speak to Dr. Pfaff about it. Since then Dr. Pfaff with Dr. Pegram and other assistance has conducted a long series of analyses and examinations with the effect of finding that bile, either human or ox-gall, dried or made into pills, increased the daily excretion and the amount of solids. I should have been glad at one time to know that ox-gall would supply the place of human bile, for my earliest case was a similar one, where after opening the gall-bladder and removing a few small stones no connection with the intestine could

be made. The patient died, I think, from the continual drainage of bile. This patient with the biliary fistula appeared at the hospital within a few days, and would hardly be known from the great improvement that has taken place since the operation. She is still discharging her bile in a small bottle she carries by her side and declines surgical interference.

As to the necessity of early operation, one of the first cases of peritonitis I ever saw was due to ulceration of a gall-stone from one of the ducts, without any jaundice. Dr. Cutler made the autopsy and found the stone.

Biliary fistulæ are not necessarily permanent; I have known them to close spontaneously and permanently in two instances after drainage. With reference to the removal of the gall-bladder, it should first be made clear that the way is open from the hepatic duct to the intestine. To have removed the gall-bladder in the case of biliary fistula described, would have converted the abdominal cavity into a gall-bladder.

DR. ELLIOT: As showing to what extent these cases are neglected I have noted the number of years the symptoms have existed in the cases I have operated on: in the first case, fifteen years; second case, eight months; fourth case, two years; fifth case, eight years; sixth case, eight months; in another case, five months; in another, ten years; in another, one year; in another, two years. These are pretty typical of the duration of the disease.

In regard to extirpating the gall-bladder, which I think is one of the most interesting questions for discussion, I have rather come to the idea of extirpating all those contracted gall-bladders Dr. Richardson speaks of. In the very acute cases, if you can get the gall-bladder out without infecting the general peritoneal cavity it ought to come out. In a very bad case it is probably pretty dangerous, and much like taking out an appendix when an abscess has formed about it. I think those acute infections are undoubtedly caused by an obstruction of the cystic duct. When the cystic duct is obstructed the gall-bladder is swollen and strained, and the process of necrosis comes about more or less as it does in acute appendicitis. There are plenty of germs present, and when the pressure comes they attack the tissue just as they do when a stitch is tied too tight. In one of Dr. Mixer's cases the colon bacillus was found in the gall-bladder. In two of the cases I have had, the bladder could have been extirpated in one, but not in the other. I think in certain diseases of the gall-bladder you can cut out a slice and sew up the rest. In one of my cases only the ulcerated part was cut out.

Suturing of the gall-bladder in proper cases must be a great blessing to the patient because it prevents the annoying drainage of bile in convalescence. I have now sutured five or six cases and they have all done well. So far as suture of the duct goes it seems to me self-evident that if you can suture a duct it is better than to leave the bile flowing with the chances of its burrowing around in the abdominal cavity. Last year I collected all the cases where it had been incised and drained. A good many of them got well, but a good many of them died from various causes. When you leave a hole in the duct the sides may or may not be in good apposition. The tamponing of them even interferes with the apposition. If you can suture the duct, I think there is no doubt as to the advisability and advantage of doing it.

THE NEW YORK ACADEMY OF MEDICINE.
SECTION ON GENERAL MEDICINE.

STATED Meeting, February 16, 1897, L. F. BISHOP, M.D., Chairman.

DISCUSSION ON STIMULATION IN ACUTE DISEASE.

The discussion was opened by DR. HORATIO C. WOOD, of Philadelphia.

After some general remarks on definition of terms and the difficulty of determining just what a stimulant is, he said that in the animal economy function was always performed at the expense of, and the life of the individual was carried on through the alternate action of, antagonistic nerves. The question then arose, Was a stimulant an agent which caused upbuilding of structure, or was it one that brought about functional activity at the expense of structure? At the present time there were remedial agents coming to the front which acted in neither of these ways, but which in some manner, not as yet clearly understood, had the effect of fortifying the system against the attacks of morbid influences. Of this nature were the antitoxins, now attracting so much attention, which displayed not only a local but a general antagonism to disease. It was also pertinent to inquire if these could be designated stimulants.

Unfortunately, he went on to say, we did not at present know our drugs well enough to apply them in the most efficient manner. Millions of dollars were expended on art galleries, libraries and museums, but not a dollar was to be had to pay men of genius for finding out the issues of life and death. He did not hesitate to say that a million dollars devoted to scientific investigation would soon revolutionize the practice of medicine in the United States.

Referring to the treatment of pneumonia, he said that there was one great principle to be borne in mind. Because the pathologist grouped a certain series of morbid conditions and called it pneumonia, it did not follow that all cases of the disease were to be treated alike. What would be salvation for one man might be death to another. It should be our aim, therefore, to carefully study the special characteristics of each particular case at the particular time at which we were called upon to treat it. In the case of an old, broken-down patient it would be our duty to hold up the flagging system. In another, of sthenic character, we would be imperatively called upon to resort promptly to venesection, or, at all events, to the use of cardiac sedatives like *veratrum viride*. We could not thus put an end to the coccus, but, after all, the coccus was only one of the factors in the case. We would, however, relieve the strain upon the right heart and enable the patient's system to bear up against the attack made upon it.

Digitalis was the one agent which had power over the nutritive process. The pneumogastric was undoubtedly the trophic nerve of the heart, and it was the peculiar function of digitalis to stimulate this. It was this power of digitalis to increase the trophic power of the nerves of the heart which made it so valuable. It was an agent which acted as a stimulus both to function and to nutrition.

Taking up the subject of acute collapse and surgical shock he said that in this class of cases there was vaso-motor paralysis principally. If alcohol had any influence upon the vaso-motor nerves, it was that of a de-

pressant, and it was not therefore indicated. In one of the early cases of death from ether, which occurred in Cincinnati, he recalled that the patient was freely dosed with alcohol. Here we have the depression of ether, *plus* the depression of alcohol, and it was no wonder that the patient died.

In typhoid fever the general consensus of opinion was that alcohol was of great service, but there was still a question as to whether alcohol could be rightly regarded as a cardiac stimulant. The most that could be said was, that it is a very mild stimulant to the heart. In this regard it could not be compared with cocaine, strychnia and other drugs. Notwithstanding this fact, however, it was undoubtedly a most useful remedy in typhoid. It was probable that it had the effect of increasing the resisting power of the tissues, and also that it is to a considerable extent germicidal. There was another very curious thing about alcohol, which set it apart from all other drugs. Opium and other agents, when taken into the system, carried their message to the nerve centres, and were then gradually eliminated; but alcohol, when once taken in, never came out. In health if we gave a man a wineglassful of whiskey or brandy, it could always be detected in the breath; but this was not the case in typhoid if the alcohol was properly given. Here, then, was a useful point in the administration of alcoholic stimulus in this disease. If in any case the odor of alcohol could be detected in the breath, we could be sure that we were overdoing the matter, and that the patient's system had not the ability to make use of all the stimulant given. In typhoid, alcohol acted not only by furnishing resisting power, but also by repairing the tissues which were being burnt up by the force of the disease.

As to the time that the use of alcohol should be begun in typhoid, he thought that this should be at the beginning of the attack, not, he said, as a stimulant, but to fulfil the other useful functions which it performs. For instance, it had a tonic effect upon the stomach and upper intestines, and enabled the patient to take more food than he could otherwise do. When given thus early it should always be administered in small quantities, and always with the food. When the time came for it later, when the vital powers were becoming exhausted and the temperature ran high (in spite of cold baths and other measures), the alcohol should be given in just as large quantities as the system could possibly utilize. Here the only guide to the amount to be given was the power of the patient to burn the alcohol up.

In speaking of other stimulants in typhoid, he said that there was nothing which acted so efficiently on the heart as digitalis. It had been found that high temperature makes this organ in a measure irresponsible to digitalis and therefore it was usually necessary to give the drug in quite large doses.

In conclusion, Dr. Wood spoke of the reinforcement of one stimulant by another, and related some of his experiments on animals in illustration of the point. This he had called the law of crossed action, a double influence being exerted upon the brain centres; and he had found that the principle had proved of practical value in the treatment of typhoid and other exhausting diseases. As an instance of its efficacy he mentioned a case that seemed altogether hopeless, in which double pneumonia supervened upon a severe attack of erysipelas. Here cocaine was administered

on top of strychnia, in the same manner as in one of his experiments where an animal was first poisoned with chloral, and in consequence of the adoption of this treatment the patient's life was saved.

DR. WM. H. THOMSON said that as to what was meant by the term stimulant it might perhaps be well to examine for a moment how agents which are not medicines, but which are really stimulants and sedatives, act upon the system. Dry heat, for instance, was an example of a pure stimulant. It was not preceded nor accompanied nor followed by any depression when used in the manner employed for medicinal purposes. Moist heat, on the other hand, was equally a pure sedative. Cold also was *per se* purely a sedative, but the sedation resulting from it was very different from that produced by moist heat, and a third term was therefore necessary to explain its action. It was an agent which caused shock, and it was the reaction from this which produced stimulation. We should, he thought, learn to discriminate more carefully as to the particular nerve functions which are affected by the most widely acting drugs, and to pick out the particular functions affected by any drug in question.

In speaking of opium he said that it was both a stimulant and a sedative, and both at the same time. The action of alcohol was somewhat different. It stimulated the whole arterial system; but while it was acting on the heart, it was also depressing the entire system of nerves, particularly the sensory nerves. Stimulation and sedation were present at the same time, and we had, therefore, to discriminate as to what functions were depressed and what stimulated.

DR. WM. H. DRAPER said he supposed there was no longer any question as to the value and necessity of stimulants in typhoid fever and pneumonia. He confessed that he had been somewhat surprised at the intimation of Dr. Wood that venesection was sometimes imperatively demanded in cases of pneumonia. For his part, he could only say that cases of this kind had not come under his observation. As to alcohol, he had long believed that it was not only a valuable stimulant, but also a food. All proper food, given in appropriate quantities, acted in stimulating the functions of the body. In the treatment of typhoid he had long been accustomed to carry out the directions for the administration of alcohol in the old Graves and Stokes system of medicine. Having referred to the conditions calling for its use, he said that he entirely agreed with Dr. Wood in his statement that there is no measure to the quantity that may be called for. As long as it was wholly taken up by the system, and was of service in meeting the indications for which it was given, we need not hesitate to pour it into the patient in enormous quantities.

The same was true as regards pneumonia. It could not be claimed that it cured the inflammation or cut short the disease. We know now that pneumonia is a specific fever, due to a specific germ, and that it is self-limited in its course. It was a disease, like typhoid, that pursued its course in spite of all treatment. What alcohol did in these diseases was to stimulate and support the system, and thus enable it to sustain itself until the disease had run its course. This mission of alcohol ceased the moment that the violence of the attack began to abate, and we should then diminish the quantity employed and give more food instead. The smell of alcohol in the

breath was a delicate test, and it was one that we should all do well to bear in mind.

DR. BEVERLY ROBINSON called attention to the different effects resulting from the use of alcohol in hospital and in private practice. In the former we had to depend mostly on other remedies, and he had used coca and strychnia successfully. He also spoke of the great value of coffee and tea as general stimulants. A great deal depended on the manner in which stimulants were administered, and he particularly advocated the hypodermic method as much more certain than that by the mouth. In addition, he referred to the importance of resorting to rectal administration in many cases, not only those in which the stomach was irritable, but in others also, as a supplementary procedure. He had seen the most remarkable results from the use, in urgent cases, of a hot enema containing black coffee and brandy. In conclusion, he said that where there was a question of local stimulation he believed in the direct local application of irritation over the cardiac region. This might be simply heat, or heat combined with mustard, and in some instances even the actual cautery might be called for.

DR. R. W. WILCOX said that it seemed probable that the antitoxins would eventually be found capable of cutting short such diseases as typhoid fever and pneumonia. We should then be approaching a long-looked-for goal, namely, their prevention.

DR. JOSEPH COLLINS spoke of the special value of the different preparations of opium in a class of acute diseases which were not self-limited, ran no definite course, and showed no disposition to result in spontaneous cure. Instances of this were acute melancholia and acute neurasthenia, and in them he had found the action of this nervous stimulant superior to that of all others.

In closing the discussion, DR. WOOD said he would like to warn those present that there is nothing so misleading as clinical results which are unsupported by physiological experiment. For instance, could any one say whether it was the coffee, or the brandy or the hot water which had been the efficient agent in Dr. Robinson's enema? As to the results claimed for opium by Dr. Collins, could it not be maintained with equal probability that the good accomplished was due principally to the hygienic rules and careful manner of living which he had no doubt prescribed for his patients? Personally, he did not believe that there was such a thing as a functional remedy or a functional disease. These terms were simply relics of our past ignorance. A line had, indeed, been drawn between functional and structural disease, but it was a line that man had drawn for himself; it was not of God's making.

Replying to Dr. Draper's criticism of his advocacy of venesection in certain cases of pneumonia, he said that in parts of Pennsylvania there was a population directly descended from sturdy Hessian stock. The people were very robust, leading healthy, out-door lives, and the local practitioners had found that when they had a case of pneumonia to deal with, unless they bled, their patient usually died. For himself, he did not meet with this class of cases in Philadelphia, any more than Dr. Draper did in New York. He would only say, in closing, that not until we learned to correct and supplement the teaching of the bedside with the teaching of the laboratory would we ever grow to be what we are really capable of.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MARCH 25, 1897.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE ATTACK ON PRIVATE INSTITUTIONS
FOR THE CARE AND TREATMENT OF CON-
SUMPTIVES.

EARLY in the session of the present Massachusetts Legislature, as was stated in the last issue of the JOURNAL, (p. 267,) a bill was introduced, entitled "An Act Relative to Contagious and Infectious Diseases and other Diseases Dangerous to the Public Health," the provisions of which, in brief, were as follows: No infectious disease to be treated or cared for in any private institution without the *unanimous* approval of the Board of Aldermen or Selectmen and the Board of Health; the diseases specified in the act are small-pox, diphtheria, phthisis or pulmonary tuberculosis, membranous croup, measles, scarlet fever, typhus fever, yellow fever and cholera. The penalty for violation is *imprisonment* not exceeding two years.

Since there is very little probability (and this statement appears to be borne out by the evidence thus far presented) of the establishment of private institutions for the treatment of small-pox, cholera, yellow fever, etc., except phthisis, it appears that the animus of the bill is aimed at private institutions for the treatment of tuberculous patients; and it should have been so labelled at the outset.

This movement is undoubtedly due very largely to an unfounded fear that such institutions might constitute a danger to the surrounding neighborhood, and this fear has been fostered and increased by exaggerated statements in regard to the infectious nature of consumption.

Boards of health in some cities have published regulations tending to make the consumptive a social leper, to placard his house, to isolate him, and to impose such restrictions as, Cornet says, "would consign him to an island in the solitary ocean."

In commenting upon the infectious nature of consumption, one of the most intelligent health officers of the present day, Dr. Russell, of Glasgow, says: "In the *academic* sense it is infectious; in the *popular*

sense it is not. . . . The popular idea of an infectious disease is one from which there is no safety save in keeping away from it. Proclaim a disease 'infectious,' and the people will pay no attention to qualifications. It is very natural. Don't go near the person, and the conditions of safety need give no trouble! Education makes no difference. The fear of infection is indiscriminating to absurdity. Typhoid fever, scarlet fever, whooping-cough, small-pox, all entail the same social ostracism."

There is no evidence to show that tuberculosis is contracted by persons while out-of-doors in the open air. The facts are all the other way, since the mortality from tuberculosis of in-door occupations is everywhere much greater than that of out-door occupations.

The bacteriological evidence also is clearly in the same direction. Experiments are abundant, showing that disease-germs exposed to the enormous dilution of the out-door air are subjected to a severe struggle for existence and soon perish under the effect of sunlight and wind and rain. Cornet, who is certainly good authority, says: "The dust of the streets where consumptives have spat, may be neglected, so far as risk is concerned." He points out that it is the dust of enclosed apartments which is dangerous only. Still further he says, in his own circular, "On the street, where spitting can scarcely be prevented, certain other circumstances diminish the risk of infection."¹

One of the institutions against which this bill appears to be aimed has been in existence about thirty years, and during this time several thousand consumptives have been cared for within its walls; and in all this time none of the nurses or attendants have contracted tuberculosis. How far it has influenced the death-rate of the neighborhood may be known from the following figures, the institution being located at the boundary line of the 21st and 24th Wards of Boston:²

Annual death-rate from consumption in Boston at large, for the six years ending May 31, 1890,	386.5 per 100,000 living
In the 21st Ward	217.6 "
In the 24th Ward	256.4 "
In the 8th Ward	671.6 "
In the 13th Ward	587.6 "

As a matter of fact, the combined death-rate from consumption, of these two wards (21 and 24) was less than that of any other ward in the city except Ward 11.

The fact that this movement is the only instance on record of any attempt to interfere with, or to limit in any way, the usefulness of hospitals intended for the relief of so widespread a disease as consumption, makes it worth while to review the position of foreign governments and medical authorities on the subject.

In Great Britain there are at present eighteen hospitals for the treatment of consumptives, four of which are in London. Of these four, three are in densely settled districts. One of them is on City Road

¹ Ueber Tuberculose, Leipzig, 1890, p. 145.

² Billings: Vital Statistics of Boston, in Eleventh United States Census Reports.

in the most densely settled part of London, a district as fully occupied as State or Milk Streets in Boston. In Burdett's "Hospitals," etc., vol. iv, he says, "This hospital occupies a very confined site, which is almost entirely covered with buildings." On one side the hospital joins a public house. The new wards for male patients at the Brompton Hospital are also separated from the surrounding houses by the width of narrow streets and alleys only.

That, not only has no action ever been taken in England toward restricting such institutions, but also that no such action has been contemplated, is evident from the fact that when a Parliamentary Commission was appointed to consider, among other points of importance, the subject of the influence of hospitals for infectious diseases on the surrounding neighborhood, no one appears to have even thought of including hospitals for consumptives in the list.

The German Government commends such hospitals in the highest terms,³ on the ground that consumption is a widespread disease, and that these establishments furnish a home where invalids may find proper care and treatment; more than this, that, with such care a considerable number of consumptives, taken at early stages of the disease, may be cured and returned to their families. In the document upon this subject recently published, the health board estimates the actual value to the empire of such cured cases as seven and one-half million marks (about \$1,850,000) annually, after deducting the cost of care and treatment. It adds, in closing, "If there is anything that is both a blessing to mankind, and also of pecuniary value to the community, it is the establishment of homes for consumptives."

In the foregoing statement no comments are intended with reference to the therapeutic treatment or the internal management of homes for consumptives existing in Massachusetts. If, as has been claimed, harm to the neighborhood exists, it seems entirely within the power of local boards of health to issue regulations to remedy the difficulty under existing statutes. The Board of Health of Boston, with commendable care for the health of the community, has issued a regulation to prevent expectoration in street-cars which has already had good effect, and only needs enforcement to produce still better results. There is, therefore, no reason why sensible regulations may not also be applied to consumptive homes and their inmates, if such are necessary.

The French League for the Prevention of Pulmonary Phthisis and other Forms of Tuberculosis, in a twelve-page pamphlet, publishes the following statement:

"We know further that the consumptive is not in the least dangerous by contact or proximity; that it is neither his body nor his breath which is hurtful; and that we can chat with him for hours, live with him for years, and even sleep in his room and give him the

most constant care, without running any serious risk, *provided we take certain precautions*, the chief of which is to collect his expectoration, and not to delay the destruction of his sputum until it becomes dry, and is disseminated as dust into the atmosphere."

RESULTS OF THE USE OF DIPHTHERIA ANTITOXIN.¹

THE Imperial German Board of Health established an official system of returns relative to the use of antitoxin in hospitals throughout the Empire in January, 1895, and the first annual report appears in the transactions of the Board (Vol. XIII, 1896).²

From the report it appears that the returns were received giving the results of the use of the *heilserum* in 9,581 cases. Out of these cases the recoveries were 7,999, or 83.5 per cent., and the deaths were 1,489 or 15.5 per cent. while one per cent. were still under treatment at the date of the report.

From the total number of deaths there should be excluded 82, which occurred during the first twelve hours after admission to hospital, of whom the remark often appears, "brought in moribund," or "hopeless from the outset."

The board concludes with the following statement: "The medical treatment of diphtheria with antitoxin (*heilserum*) marks a decided advance in the domain of therapeutics. Favorable results are more often noted from its use than are known to occur under previous methods approved by science. The secondary effects occasionally observed are of slight importance when compared with the general advantages of its use."

The fatality of diphtheria in German Hospitals is shown (in the same report) to have been as follows:

CASES OF DIPHTHERIA AND CROUP.

	Admitted.	Deaths.	Fatality.
1883	9,622	2,777	28.9%
1884	10,783	2,716	25.2
1885	10,802	2,532	23.4
1886	11,900	2,918	24.5
1887	11,968	2,838	23.7
1888	10,921	2,839	26.0
1889	13,139	3,344	25.5
1890	12,770	3,647	28.6
1891	11,793	3,201	27.1
1892	13,895	4,115	29.6
1893	19,603	5,903	30.1
1894	20,728	5,348	25.8
1883-94	157,724	42,178	26.7%
April, 1895, to March, 1896	9,581	1,489	15.5%

The fatality by ages was 44.8 per cent. for children under one year; 37.8 per cent. from one to two years; and so on to nothing at the older ages of life.

The value of antitoxin as a life-saver depends largely on the promptness of its use, as is shown by further figures. Of those treated before the end of the second day of illness, the fatality was 7.9 per cent.; of those treated after the sixth day, about 25-26 per cent.

¹ Ergebnisse der Sammelforschung über das Diphtherieserum für die Zeit vom April, 1895, bis März, 1896. Dr. Dieudonné.

³ Ein Beitrag zur Beurtheilung des Nutzens von Heilstätten für Lungenkranke, published by the Imperial Health Office of Germany, Berlin, 1896.

The following figures are presented from other sources:

Author.	No. of Cases.	Fatal ity %	1st day.	2d day.	3d day.	4th day.	5th day.	6th day.	After 6th day.
Welch.	14,891	14.2	2.3	8.1	13.5	19.0	29.3	34.1	33.7
Hilbert.	2,428	18.3	2.2	7.6	17.1	23.8	33.9	34.1	38.2
Amer. Fed. Soc.	5,794	12.3	4.9	7.4	8.8	20.7	35.3
Austrian Health Authorities.	1,103	12.6	8.0	6.6	9.8	25.5	28.8	30.7	21.0
Mass. Bd. Health	562	12.10	0	9.7	8.7	15.4	22.2	20.0	33.3
Boston " "	647	14.39

The majority of the cases that were reported by the Massachusetts State Board of Health occurred in private practice. The majority of the cases that were reported by the Boston Board of Health occurred in hospitals. The percentage relating to the fatality occurring according to the day of treatment with anti-toxin in the line for Massachusetts State Board of Health, refers only to cases in which a positive diagnosis was made by culture from the throat. The previous fatality from diphtheria and croup in Massachusetts (1891-94) had been 28.3 per cent. (13,332 notified cases, with 3,768 deaths).

THE BACILLUS OF PLAGUE.

THE report of Dr. H. T. Wilson, of the Hoagland Laboratory, who for some time past has been experimenting with plague microbes at the request of Commissioner Emery, the head of the Brooklyn Health Department, has just been made public. The bacilli came from Yepin, China, and were sent by Dr. W. F. Arnold, of the United States Navy, who is now attached to the Pacific Squadron. In order to test their activity he first inoculated several rabbits, all of whom rapidly succumbed to the disease originating from them. Test-tubes containing cultures of the bacilli in bouillon were then subjected to varying degrees of temperature, and it was found that up to 58° Centigrade the bacilli flourished and multiplied. At 59° their vigor became impaired, and at 60°, or about 120° Fahrenheit, their life became extinct. This relationship to heat reminds us that epidemics of the plague have not been observed south of 19° of latitude north. In the case of bits of paper, cloth and other material infected with the bacilli and then placed in a dry closet the result was the same, the germs not being able to survive a temperature of 60° C., or higher. As a result of his investigations Dr. Wilson concludes that the death-point is one or two degrees higher than that of the bacteria of this class of diseases in general, and that unlike cholera germs, sunlight and dryness cannot be relied upon to limit the life of this bacillus. He recommends that rags, nails, ballast and general merchandise coming from infected ports should be subjected, at either the port of departure or the port of entry, to a thorough system of disinfection. He has made experiments only with carbolic acid, and

with this agent he has found that an exposure for two hours to a one-per-cent. solution suffices to destroy the life of the bacillus.

MEDICAL NOTES.

ANESTHETICS AND THE LAITY.—Governor Black, of New York, has signed the bill making it a felony for a person other than a duly licensed physician to have an anesthetic on his person with the intention of administering the same to another person, and makes the finding of the same on the person by any one presumptive evidence of guilt.

PROFESSOR SENN'S GIFT TO THE NEWBERRY LIBRARY.—Prof. Nicholas Senn has purchased the entire library of the late Prof. DuBois Reymond, and presented it to the Newberry Library, Chicago. The collection consists of 14,000 books, chiefly on physiology and allied subjects, and will form a very important addition to the medical equipment of the library.

THE BEST RECORD FOR HIS AGE.—The Dublin correspondent of the *Lancet* is authority for the statement that a man named James Loder, eighty-two years of age, covered thirty-three feet in three standing jumps at a recent athletic contest in Cork County. Loder weighs one hundred and twelve pounds, and it is stated that his father lived to the age of one hundred and ten years.

CALCUTTA AND ITS SANITATION.—"If any town," says the *British Medical Journal*, "ever deserved the severe visitation of an epidemic for its sanitary sins it is Calcutta. Moreover, they have defied interference, relegated the sound advice of their medical officer to the waste-paper basket, and continued a system which may have done very well for India in the days of Hindu supremacy, but is totally at variance with modern methods and needs."

ORDINANCE AGAINST COCAINE.—It is reported that the victims of the cocaine habit have become so numerous in Chicago that an ordinance has been introduced prohibiting the sale of remedies for catarrh and other diseases, which contain cocaine. In the last two months over forty victims of the drug have appeared in police courts and elsewhere. Several of them have been well-known men and women, who say they were brought to their present condition by using catarrh cures.

HANGING AFTER TRACHEOTOMY.—Dr. Reineboth, of Halle, according to the Berlin correspondent of the *Medical Press and Circular*, reports the case of a man who, in consequence of a sarcoma threatening suffocation had tracheotomy performed and a canula inserted. He got tired of life, however, and put an end to it by hanging, placing the strangulating cord above the canula so that respiration would still go on unimpeded. Death appeared to have taken place rapidly. The case shows that death by hanging is not brought about by preventing respiration, but by

pressure on the large vessels. The position of the body also was such that with continued consciousness the man had not time to get on his feet again. It appears from this that loss of consciousness was as rapid as in ordinary hanging. The autopsy showed anemia of the cerebrum, extreme fulness of the arteries of the base, slighter fulness of those of the pia mater, hyperemia of the pons and medulla. Death by hanging without closure of the air-passages is not unknown in literature, but it would be difficult to find a parallel to the above.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, March 24, 1897, there were reported to the Board of Health, of Boston, the following numbers of cases of acute infectious disease: diphtheria 64, scarlet fever 43, measles 200, typhoid fever 7.

THE WARREN CHAMBERS.—This new physicians' office-building at 419 Boylston Street, Boston, will be open to physicians for inspection on Tuesday, March 30, 1897, from one to six.

THE FLOATING HOSPITAL.—The management of the Floating Hospital Fund announce that the fund has become sufficient for the purchase of the barge *Clifford*, which they have decided to buy and fit up for their use. The price to be paid for the barge is \$3,500. A ward containing twelve or more beds is to be fitted up for the sick cases.

DR. NORTHRUP LECTURES AT THE BOSTON INFANTS' HOSPITAL.—At the opening of the new lecture-room of the Boston Infants' Hospital on March 17th, Dr. W. P. Northrup, Professor of Children's Diseases in the Bellevue Medical College of New York, addressed by invitation the students of the Harvard Medical School on "Tuberculosis in Children." The lecture was illustrated by lantern slides. The lecture-room has lately been enlarged so that an audience of one hundred and fifty can be seated, and is used for lectures to nurses and to the Harvard medical students.

THE MAYOR OF SPRINGFIELD PROTECTS EXPECTORATION.—Mayor Dickinson of Springfield, Mass., has vetoed an ordinance passed by the city council forbidding expectoration in public places. The editor of the *Springfield Republican* voices intelligent public opinion on the subject in the following terms: "The more Mayor Dickinson's veto of the anti-spitting ordinance is considered the more indefensible it appears. The grounds upon which it was based were utterly frivolous. Here was a reasonable measure wholly in the interest of public health and decency. It had been petitioned for by a large number of our most intelligent citizens, including many physicians. It passed both boards of the city council by large majorities. The enforcement of such an ordinance in the reasonable and fair spirit with which other city ordinances are enforced would have done injustice to no well-meaning and law-abiding person.

There was no call for the mayor to interpose his veto. He has offered an affront to the decent people in the community and pleased the loafers."

NEW YORK.

MEDICINE AND MURDER.—At a meeting of the Society of Medical Jurisprudence held March 8th Stephen C. Baldwin, Esq., a youthful member of the bar, read a paper with the rather startling title, "Are the Doctors all Criminals?" His contention was that probably every physician or surgeon of any experience in New York had committed manslaughter in the second degree, as that crime is defined in the Penal Code. "Section 193 of the Penal Code," he said, "defines manslaughter in the second degree as causing, by any act, procurement or culpable negligence, the death of any person. These words are very plain, and no element of premeditation, design or intended criminality is necessary." After elucidating this idea and citing a number of supposititious cases in illustration, he expressed the opinion that the law should be so amended that a physician or other person, acting according to his best judgment, should not be held guilty. The discussion which followed the reading of the paper showed that the profession is not seriously alarmed at the danger to which it is thus exposed, and that a modification of the law is hardly called for. Dr. Morrell, who opened it, was of the opinion that the statute was really and properly aimed at quacks and other incompetent practitioners, and that it exerted a salutary influence in causing physicians to exercise greater care in their cases. John Sabine Smith, Esq., said that there were many laws on the books that are not intended to be enforced except in extreme cases. The present law is apparently perfectly plain in intent, and this intent would without doubt be clearly defined to any grand or petit jury before which a mischievous person might attempt to make a case.

THE NEW YORK COUNTY MEDICAL ASSOCIATION.—At a meeting of the New York County Medical Association held March 15th, a committee was appointed to confer with similar committees of the Academy of Medicine and the County Medical Society in regard to the abuse of medical charity in the hospitals and dispensaries. Other special committees were also appointed for the following purposes: To wait upon Mayor Strong with the request that he should appoint a medical man to fill the next vacancy on the Board of Commissioners of Public Charities; to wait upon Mr. J. Pierpont Morgan with the request that, in view of the already ample provisions at present existing in the city for the class of cases which it is designed to benefit, he should reconsider his proposed offer of \$1,000,000 for the erection of a new building for the New York Lying-in Hospital. The principal paper of the evening was by Dr. A. E. Gallant, who advocated the use of balsam of Peru and castor oil as a surgical dressing, the efficacy of which, he said, had been demonstrated in 28,000 dispensary cases, including

burns, wounds, ulcers, abscesses, etc. The balsam-oil was applied on pads of gauze, with an external covering of oiled silk, rubber tissue or starch bandage. It is claimed that by its continuous sponge-like action this dressing causes perfect drainage, and thus saves the busy surgeon a great deal of time by rendering antiseptic precautions unnecessary. The balsam is used in the strength of from 20 to 30 minims to the ounce of oil.

MEDICAL INSPECTORS FOR THE PUBLIC SCHOOLS.

— At a meeting of the Board of Health, held March 16th, 134 medical inspectors were appointed for the public schools, in accordance with the provision recently made by the city authorities at the recommendation of the Health Department, endorsed by the Board of Education. Dr. A. Blauvelt, formerly Assistant Chief of the Bureau of Contagious Diseases, was appointed Chief Inspector, at an annual salary of \$2,500.

SMALL-POX IN NEW YORK.— In consequence of the discovery of three cases of small-pox, one of which turned up at the New York Hospital, the physicians of the vaccination bureau of the Health Department have been making a tour of the various lodging-houses, 116 in number, with a capacity of from 15 to 400 lodgers, and on the night of March 15th more than 5,000 individuals were vaccinated by them. While the Board of Health cannot force a person to be vaccinated, the sanitary code provides that no building can be used for lodging-house purposes in which the inmates have not conformed to the rules of the Board, which include vaccination. The cases of small-pox mentioned are the first that have been reported in the city for a considerable time.

REAR TENEMENTS MUST GO.— A bill was introduced in the State Senate at Albany on March 16th, prohibiting the erection of any tenement or dwelling-house on a lot in the rear of another dwelling, and also demands the removal of all such buildings now existing within six months after the passage of the act. It will perhaps be remembered that a very large proportion of the tenement-houses which have been condemned by the Board of Health, on account of the high rate of mortality in them, since the authority for such action was granted the Board by the Legislature, have been rear buildings.

Miscellaneous.

ORDINANCE CONCERNING EXPECTORATION.

THE Board of Health of the village of Saranac Lake, N. Y., issued the following preamble and ordinance several months ago:

Whereas, The expectorated matter discharged by persons having any disease of the air passages (lungs, throat, mouth and nose) usually contains germs capable of communicating the same disease to other persons; therefore, be it

Resolved, That the Board of Health of the Village of Saranac Lake does expressly declare, that the indiscriminate discharge of such expectorated matter, in any place where it may be the means of communicating disease to other persons, is a nuisance dangerous to public health, and that this Board does hereby adopt the following:

SECT. 1. All persons who expectorate in consequence of any disease of the air passages (lungs, throat, mouth and nose), are positively forbidden to spit or discharge such expectorated matter upon the floor of any house, store, church, schoolhouse, hall, or upon any sidewalk, or in any dooryard, or other place where such matter may be the means of communicating disease to other persons.

SECT. 2. Any person who shall violate the first section of this ordinance shall be liable to a penalty not exceeding five dollars for the first offence, nor more than twenty-five dollars for a subsequent offence, which penalty shall be imposed by and at the discretion of the Board of Health.

NOTE.— Hotels, inns and boarding-houses should provide suitable cuspidors for the accommodation of their guests. Cuspidors should be thoroughly cleansed and disinfected daily and should contain a small amount of germicide solution.

Persons who have occasion to expectorate when on the streets should carry small pieces of cheese-cloth, which, after being used, must be preserved, and burned with as little delay as possible. Chinese paper napkins or toilet paper will answer a similar purpose. The casting of any of these aside, after use, where they may affect others, will be regarded as a violation of the ordinance.

CAUTION.— Handkerchiefs should never be used to receive expectorated matter. If so used they must be boiled, or soaked in a germicide solution, with as little delay as possible, and never be put with the other articles to be landried.

The Chairman of the Board, Dr. E. S. McClellan, writes us under date of the 17th inst.:

"The moral sentiment in support of this ordinance is so general here that we have not found it necessary to impose a single penalty. A first notice usually brings the transgressor to a proper sense of duty, with the assurance of future good behavior."

RESOLUTIONS OF THE BOSTON MEDICO-PSYCHOLOGICAL SOCIETY ON THE REPORT OF THE COMMISSION TO INVESTIGATE THE PUBLIC CHARITABLE AND REFORMATORY INTERESTS AND INSTITUTIONS.

At a meeting on the 18th of March, 1897, of the Boston Medico-Psychological Society, it was

Resolved, That the Society unanimously approves and heartily endorses the recommendations made to the Legislature by the special Commission to investigate the Public Charitable and Reformatory Interests and Institutions of the Commonwealth, as presenting for the first time a systematic and wise plan for caring for the dependent and criminal classes in the most economical, humane and scientific manner.

Resolved, That while endorsing all the measures of reform which this Commission proposes, the Society, taking special interest in the care and treatment of the insane, feels most strongly the wisdom of placing all the insane under the care of the State, and of appointing a Commission in insanity, to consist in part of men skilled in the knowledge of mental diseases, believing that such measures will ensure the most humane care of the insane and will advance our knowledge as to the best method of the prevention and treatment of mental diseases.

Resolved, That the Society urges upon the Legislature the pressing need for the enactment of such laws as may carry into effect the recommendations of the Commission, especially the recommendations relating to the insane.

HENRY R. STEDMAN, M.D.,
GEORGE F. JELLY, M.D.,
PHILIP COOMBS KNAPP, M.D., } Committee.

METEOROLOGICAL RECORD

Deaths reported 2,694: under five years of age 862; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping cough, erysipelas, diarrheal diseases and fevers) 232, acute lung diseases 534, consumption 322, diphtheria and croup 86, diarrheal diseases 42, scarlet fever 24, whooping-cough 23, typhoid fever 19, measles 19, cerebro-spinal meningitis 11, erysipelas 8.

From scarlet fever New York 13, Boston and Chicago 4 each, Baltimore, Cincinnati and Providence 1 each. From whooping-cough New York 10, Chicago 5, Cleveland 2, St. Louis, Boston, Washington, Fall River, Lowell and Springfield 1 each. From measles New York 9, Chicago 6, Cincinnati, Worcester, Lowell and Taunton 1 each. From cerebro-spinal meningitis New York 6, Somerville 2, Brockton, Fitchburg and Waltham 1 each.

In the thirty-three greater towns of England and Wales with

an estimated population of 10,992,524, for the week ending March 6th, the death-rate was 18.1. Deaths reported 3,822; acute diseases of the respiratory organs (London) 307, whooping-cough 103, diphtheria 67, measles 59, diarrhea 45, fever 26, scarlet fever 25, small-pox (London) 6.

The death-rates ranged from 24.2 in Blackburn to 12.6 in Derby; Birmingham 21.0, Bradford 16.9, Bristol 18.6, Cardiff 15.9, Huddersfield 13.9, Hull 19.5, Leeds 20.2, Leicester 15.6, Liverpool 19.4, London 17.4, Manchester 23.0, Newcastle-on-Tyne 17.5, Nottingham 18.1, Plymouth 21.4, Sheffield 17.8, Swansea 15.6, West Ham 15.4.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 13, 1897, TO MARCH 19, 1897.

FIRST-LIEUT. CHAMPE C. McCULLOCH, JR., FREDERICK P. REYNOLDS and MADISON M. BREWER, assistant surgeons, are ordered to report in person to the president of the examining board appointed to meet at Fort Leavenworth, Kansas, for examination for promotion.

A board of officers to consist of MAJOR HENRY McELDERRY, surgeon; MAJOR JOHN M. BANISTER, surgeon; CAPTAIN WILLIAM F. LIPPITT, JR., assistant surgeon, is appointed to meet at Fort Leavenworth, Kan., on Tuesday, April 13, 1897, at 10 o'clock A. M., for the examination of such officers of the Medical Department, as may be ordered before it to determine their fitness for promotion.

BRIG.-GENERAL GEORGE M. STERNBERG, surgeon-general, and LIEUT.-COL. DAVID L. HUNTINGTON, deputy surgeon-general, are detailed to represent the Medical Department of the Army at the Twelfth International Medical Congress to be held in Moscow, Russia, August 19 to 26, 1897.

Leave of absence for one month is granted MAJOR CURTIS E. MUNN, surgeon, Benicia Barracks, Cal.

CAPTAIN PAUL CLENDENIN, assistant surgeon, is transferred from Fort Warren, Mass., to Key West Barracks, Fla., to relieve CAPTAIN JEFFERSON R. KEAN, assistant surgeon, who is transferred to Fort Warren, Mass.

CAPTAIN GEORGE MCCREERY, assistant surgeon, ordered to Fort Warren, Mass., for temporary duty, in addition to his present duties.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE FIFTEEN DAYS ENDING MARCH 15, 1897.

MURRAY, R. D., surgeon. Granted leave of absence for one day. March 17, 1897.

GEDDINGS, H. D., passed assistant surgeon. Upon adjournment of Sanitary Conference at Venice, Italy, to proceed to Marseilles, France, for special temporary duty. March 10, 1897.

WERTENBAKER, C. P., passed assistant surgeon. Granted leave of absence for seven days from March 13, 1897.

PROMOTION.

C. H. GARDNER and RUFERT BLUE, assistant surgeons, commissioned as passed assistant surgeons. March 3, 1897.

MÜTTER LECTURESHIP OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

The next course of ten lectures instituted by the late Professor Thomas Dent Mutter, M.D., LL.D., on "Some Point or Points in Surgical Pathology" will be delivered in the winter of 1899-1900, before the College of Physicians of Philadelphia.

The compensation is \$600. The appointment is open to the profession at large. Applications stating in full subject of proposed lecture must be made before October 1, 1897, to Committee on Mutter Museum.

JOHN H. BRINTON, M.D., Chairman,
N. E. Cor. 13th and Locust Streets, Philadelphia, Pa.

BOOKS AND PAMPHLETS RECEIVED.

Observations on the Treatment of Epilepsy. By A. N. Williamson, M.D. New London, Conn. 1895.

Shortening the Round Ligaments; Indications, Technics and Results. By George M. Edebohls, A.M., M.D. Reprint. 1896.

Ninth Report of the State Board of Health of the State of Maine for the Two Years ending December 31, 1895. Augusta, 1897.

Acquired Nystagmus in Occupations other than Coal Mining, with Cases and Remarks. By Simeon Suell, F.R.C.S. Ed. Reprint. London. 1896.

Lecture.

WHEN TO CALL A SURGEON IN APPENDICITIS.¹

BY GEORGE W. GAY, A.M., M.D.,
Surgeon to the Boston City Hospital.

THE remarks which I shall present to you this evening are intended especially for the family physician, who does not operate himself, and who does not wish to assume the sole responsibility of deciding those important questions peculiar to appendicitis. It falls to the lot of the general practitioner in the great majority of instances to see the victims of this malady in its early stages, and it is scarcely too much to say, that not infrequently the result is largely determined by the measures adopted at that time. It is not worth while to enter upon a discussion as to whether appendicitis is a surgical or medical affection. Suffice it to say, that the general practitioner, from the very nature of his relation to the public, is obliged to meet, to accept, and to treat these patients during the earlier part of the attack according to the best of his ability, and with the resources at his command. For these reasons any suggestions or information which the surgeon can furnish from his standpoint renders the physician more efficient, and better enabled to cope with one of the most formidable maladies of the present day.

Ever since Dr. R. H. Fitz presented his justly celebrated paper to the profession, now more than ten years ago, the subject of appendicitis has occupied a foremost rank in the medical societies and in the medical literature of this country. Physicians and surgeons have vied with each other in studying and in reporting cases, with a view to deciding the many disputed points in relation to the cause of the disease, the treatment and its results. The practitioners are few who have not been called upon to treat these cases, and who have not had reason to feel that much is still to be learned before a uniform standard of treatment will be attained. The last word has not been spoken or written; there are still mooted points to be settled; and for this reason the writer felt that he could not better occupy your time and attention, than by briefly indicating some of the conditions and circumstances under which the general practitioner may very properly and wisely seek the advice, the support and the aid of the practical surgeon.

Much has been learned from the family physician in the past, and will continue to be in the future, in regard to the early symptoms, the course of the disease, the results of the so-called "expectant" treatment, and many other points. While from the very nature of things there can be no hard and fast custom in these matters, yet, as a rule, these patients require both medical and surgical treatment; so they should receive the services of the surgeon in addition to those of the physician. It goes without saying, that many patients cannot command the services of an expert, but must rely upon the aid which is at hand. The heartiest co-operation should, and I believe does, exist between the physician and surgeon in the management, not only of this disease, but of all others in which the services of both may be required. The best interests of the patient, of the profession, and of

the public all lie in the same direction, and the more thorough and cordial is the understanding upon these matters, the better will it be for all concerned.

It is hardly necessary for me to say that I do not belong to the radical wing of the profession, which maintains that every case of appendicitis demands operative interference. The final and conclusive test of experience would seem to prove beyond a reasonable doubt the fallacy of that plan of treatment. According to Hawkins, of 264 cases of appendicitis, 190 ran their course without suppuration. Dr. Fitz thinks "that from two-thirds to three-fourths of all cases are likely to recover from the immediate attack without surgical treatment." Dr. M. H. Richardson says that of the cases to which he is called to decide the question of operation, about half recover without it. Dr. McBurney believes that considerably more than half of the patients will recover from the first attack without operation.

In 46 consecutive cases under the reader's care at the Boston City Hospital an operation was performed 24 times, with nine deaths. Of course, only the severest cases received radical treatment. The lighter cases, 22 in number, were treated "expectantly," and all recovered.

Now, unless a fairly large proportion of all these patients who recover without an operation are again seized with this disease in the near future, it will be difficult to convince any considerable number of our fellow-practitioners, that every one of those patients should have been treated by abdominal section. Many individuals in our midst including several in our own profession, have been through one or more attacks of appendicitis in years long gone by, and have to all appearances reached a safe and permanent recovery without operation. It is difficult for the ordinary practitioner to understand why a radical operation should be universally resorted to in any affection, when about 50 per cent. of the victims will in all probability make a safe and permanent recovery without it. As human nature is at present constituted, a large proportion of our patients will very likely prefer to run their chances of the future, rather than submit to an operation, not wholly devoid of danger, for a single attack of appendicitis which is neither severe nor prolonged. I am fully aware that occasionally an apparently mild case suddenly assumes an alarming and dangerous condition, but I question if this event occurs often enough to justify operation in every instance. At all events, the experience of the past ten years has not yet taught any such lesson to a majority of our best men, who have the most to do with this malady. What the future may have in store for us on this point remains to be seen.

The ground taken by the reader is, that patients with appendicitis, who are in collapse, or who are not sick enough to go to bed, or in whom the symptoms are mild and not prolonged, or, if severe at first, show a decided change for the better within forty-eight hours, do not require an immediate operation. The larger proportion of cases coming between these extremes may or may not require surgical interference, according to circumstances. It is for us to study each case carefully by all the light we can get, and try to decide judiciously as to which cases require operative treatment, and which can be safely carried through without it.

As a preliminary to our subject a few words upon

¹ A lecture delivered in the Graduates' Course of the Harvard Medical School, November 5, 1896.

the diagnosis of appendicitis may be permitted. It is pretty well settled in the minds of the profession that peritonitis in the male means appendicitis, whatever may be the peculiarity of the symptoms. The exceptions to this rule are so uncommon that our treatment need not be influenced thereby. Occasionally a volvulus, an intussusception, a band, or twist of the bowel, or a mesenteric thrombus may be found instead of a lesion of the appendix, but the symptoms will be grave, and an operation will be as certainly indicated, which of itself will, in all probability, clear up the diagnosis, as well as give the patient the best possible chance for recovery.

The most reliable and important symptoms of acute appendicitis are pain and tenderness in the abdomen. They are always present to a greater or less degree in the early stage of the affection, and the latter persists so long as the active process is going on. Of such vital importance is tenderness in the acute stage as a factor in the diagnosis, that its absence would make one hesitate to call the disease appendicitis, even were the other symptoms present to a marked degree. The only time the writer ever opened the belly for supposed appendicitis without finding it, was in the case of a middle-aged gentleman, who had suffered severely for three or four days with pain in the bowels, requiring repeated doses of opiates. The abdomen was distended and tympanitic; there was paresis of the bowels, with obstinate constipation, grayish, shrunken skin, pinched features and prostration. He was evidently a very sick man, and apparently suffering from general peritonitis. For the past few years he had had several attacks of a similar character, but of less severity. There was little or no tenderness of the abdomen. The operation revealed a healthy appendix. The intestines were markedly congested, but free from lymph or adhesions. At the autopsy nothing further was found to account for the symptoms. There was neither band, twist, intussusception or other lesion found upon a careful examination. The only symptom wanting in this case to complete the clinical picture of appendicitis was tenderness. Its absence was fatal to the diagnosis.

Pain and tenderness then are the principal symptoms of appendicitis, which seldom fail to be present from the beginning; and their severity and persistency, as a rule, are an index to the gravity of the attack.

Tenderness is the main feature which distinguishes appendicitis from colic or functional affections of the abdominal organs. The pain is frequently as severe in the latter as in the former, but it is not as persistent nor as prostrating in the functional as in the inflammatory affection.

In the early stages of appendicitis the pain is located in the vicinity of the navel rather than in the right inguinal region. This fact is very misleading to many physicians, who naturally expect to find it referred to the usual seat of the appendix. It is to be distinctly remembered, that both the pain and the tenderness may not be located in the region of the appendix for two or three days after the commencement of the disease. If, however, the patient is very sick and steadily growing worse, be assured that these symptoms will sooner or later declare themselves in an unmistakable manner, thereby removing all doubt as to the character of the disease.

By way of summary it may be said, that the cases

are rare in males and in young girls in which sudden, acute abdominal pain accompanied by tenderness on deep pressure upon the right side of the median line does not indicate a lesion of the appendix. The writer submits that this is a good working rule for every-day practice. The exceptions are so uncommon, and an early diagnosis is so important, that an occasional error resulting from its adoption will be readily overlooked by all concerned.

Rigidity of the abdominal muscles, more marked upon the right side, is an important symptom; and so is intestinal paresis, as indicated by inability to pass off the gas by the rectum. Pulse, temperature, vomiting, restlessness and prostration will also demand attention. These symptoms, however, are all subordinate in importance for purposes of establishing a probable diagnosis to those above mentioned, namely, pain and tenderness, which alone are worthy of the first and most careful consideration. A person may be very sick with appendicitis, and still have nothing the matter with him, if the pulse and temperature alone are depended upon as an indication of his condition.

Occasionally a case is met with in which the symptoms are so slight and so evanescent, that it is only after observation of repeated attacks that the character of the affection can be ascertained with reasonable certainty.

Since this paper was written, a young woman was admitted to the City Hospital with what was supposed to be appendicitis. She had the symptoms of a pretty severe general peritonitis of two days' duration. It was the third attack within two months. There was sudden, severe pain in the abdomen, followed by vomiting, retention of flatus, fever and restlessness; tenderness was more marked on the left side of the median line. She had severe exacerbations every twelve hours.

On opening the peritoneal cavity the appendix was small, moderately congested and surrounded by recent adhesions. It was evidently not the focus of the present trouble, as the greater amount of congestion and discoloration was located in the region of the umbilicus. Here was found a firm band attached to a coil of the small intestines, and running down towards the pubes. This band was separated from the bowel, the appendix was removed, and the wound closed completely. She has made a satisfactory recovery. The only peculiarity of the symptoms in this case at the time of the operation, was that she did not seem to be quite as tender over the appendiceal region as you would expect her to be.

This case is mentioned merely to show, that occasionally on opening the peritoneal cavity for supposed lesion of the appendix, we do not find the exact conditions that the symptoms would lead us to expect. It does not militate against the treatment in any way, but on the contrary it illustrates the wisdom of exploratory operations under certain circumstances.

The diagnosis of probable appendicitis having been established, the treatment of the patient is the next question to engage the attention of the family physician. This is the time, in the majority of instances, when he needs and should have the aid and the support of the surgeon. I want to say here and now in the strongest possible manner, that every case of probable or possible appendicitis in which the symptoms are grave or protracted had better be seen by one who is familiar with the disease and who is accustomed to operating for its relief, for the following reasons: (1) to confirm or establish the diagnosis; (2) to divide

and share the responsibility; (3) to get at the real condition of the patient at the earliest moment practicable, that his measure, so to speak, may be taken before he gets into a dangerous, and hence unsatisfactory, condition; (4) that the patient may have the benefit of early observation by the one who is to decide upon the necessity of an operation and the proper time for its performance; and, finally, for the satisfaction of the friends, as well as for the protection of the regular attendant in the future in case the result should be disastrous. It is seldom that a useless or premature consultation is called in this disease. Too often the surgeon, through no fault of the family physician, is summoned too late to be of any service, except to convey to the anxious friends a statement of the unfortunate condition of affairs, and to offer what consolation he may under the circumstances. Early, and if necessary, frequent consultations should be the rule in all but the very lightest cases of appendicitis.

The laity are now so familiar with this affection, and have such a horror of it, and justly so, that any error in judgment in this direction is not laid up against us. Hence I would urge all physicians who are not pretty familiar with this disease, and who do not feel reasonably certain of their patient's condition, to call a surgeon early. Put him on to the case in line with yourself; keep him posted as to the progress of the symptoms, and summon him whenever you are in doubt as to the true state of affairs. See your patient every six to twelve hours. Because he is comfortable at one visit, do not take it for granted that he will be at your next.

Look out for exacerbations. They mean a fresh extension of the infection, a further invasion of the peritoneum, and a greater menace to the welfare of the patient. You are dealing with one of the most treacherous of known diseases, insidious in its manifestations, uncertain in its career, and liable to sudden changes, which at any moment may put the patient in a condition of extreme peril. Given a case of appendicitis of any severity, your vigilance cannot be too active nor your precautions too complete to guard the patient against the various accidents and misfortunes liable to befall him.

I may here be permitted to digress for a few moments to speak more at length upon the proper treatment to be pursued in the earliest stages of this affection. You are called to a person suffering from pain and tenderness in the abdomen, which in your opinion indicate a lesion of the appendix. What shall be your first treatment? Will you give laxatives or an opiate? Many physicians would recommend the former, most surgeons the latter. If the pain is at all severe, I not only advise, but I urge you to give sufficient morphine under the skin to relieve the pain. That is the symptom which you are called upon to treat, and for the time being it overshadows everything else. Relieve the immediate distress, and then take time to consider as to what further treatment is necessary. The amount of opiate required to effect this object varies in different cases, and is often an index of the severity of the attack, and of the danger to be apprehended.

In fortunate cases the pain once subdued in this manner does not return, as was shown in the following instance: A young gentleman was recently seized with severe pain in the bowels, while in the recitation-room at college. He was obliged to leave the class, and started for home. The pain became so unbearable,

that he got off the electric car, crawled into the nearest physician's office, threw himself upon the floor, and rolled in agony. A half-grain of morphine under the skin relieved him completely in a short time. He at once entered the City Hospital, and remained about a week, having no further trouble, save a slight tenderness or uneasiness in the appendiceal region upon deep pressure or in certain movements.

This gentleman was naturally anxious about the future. He was told that in our opinion he was liable to have another attack at almost any time, and that it might be even more severe than the present one, and less readily amenable to treatment. It was for him to decide whether he would risk it or not. Our advice was that he should wait a few weeks or until every vestige of this attack had passed away, and then have the appendix removed. The operation was done inside of a month, and the appendix was found to be the seat of marked catarrhal inflammation. He made a quick and satisfactory recovery.

Now, no judicious physician could hesitate for an instant on purely theoretical grounds to give morphine, or some other quick opiate, in cases like this. To abolish the pain, remove suffering, and thereby save nerve force is plainly our first duty. As it requires a long time for sufficient opiate to be absorbed from the stomach of a person in great pain, it is far better to put it under the skin in the form of morphia. It is thus quickly and surely taken up, and we are not long left in doubt as to its effects.

So much for the initial treatment of appendicitis in the severe cases. What shall it be in those instances, of which there are many, where the pain is moderate in severity, and hence the necessity for immediate relief is not so urgent? Shall opium or laxatives be given? Experience teaches us beyond a doubt, that many cases recover under both methods of treatment; and yet, in my opinion, there is a very decided preference in favor of the former or sedative plan. Having been a victim to this disease at intervals, for eighteen years, and having twice undergone laparotomy for its relief, the writer feels that he can express an opinion upon this point with some confidence. While relief may follow the administration of castor-oil or other laxative in the lighter cases, yet the severe ones are more often made worse by such medication. Opium judiciously given seldom, if ever, does harm under these circumstances; laxatives oftentimes do great injury, and may turn the scale against recovery. There can be little doubt that the former is the safer and better plan. The writer claims that opiates will relieve every case that laxatives or cathartics will, and very many cases that the latter will not relieve. For these reasons he cannot urge you too strongly to depend upon opiates for the relief of pain in the first stages of appendicitis. It is claimed that opiates mask the symptoms in this affection, and may thus mislead the physician as to the patient's real condition. While this may be true to a limited extent, yet any one accustomed to seeing and studying this disease can form a reasonably correct opinion of the case by making due allowance for the effects of the drug. In rare instances a few hours' delay might be desirable, before a final decision is reached. At all events this objection is not often a valid one in every-day practice.

For the pain of appendicitis, then, opiates are our main reliance in our earliest stages; but we must not

depend upon them for too long a period, or the golden opportunity for permanent relief may pass away never to return. Here comes in one of the most difficult questions of the whole subject for decision, to wit, When shall medical treatment be supplanted by surgical, or, in other words, when shall an operation be resorted to?

The indications may be briefly stated as follows: In very severe cases an operation is called for within twenty-four hours, or, at the outside, forty-eight hours from the commencement of the seizure. In cases of moderate severity, with no signs of amelioration of the symptoms on the third or fourth day, an operation is usually indicated. In relapsing cases, in from seven to fourteen days, according to the urgency of the symptoms. In recurring cases, after the first attack is entirely recovered from, say in from four to eight weeks, if the symptoms were severe, or after the second attack if the symptoms were only of moderate severity. It is to be borne in mind that these periods are only approximate, and not intended to be exact by any means, as each case is to be decided upon its own merits and manifestations. No affection calls for more careful consideration, a clearer understanding and calmer judgment than appendicitis.

It may be said here, that persons having a damaged appendix should be careful about travelling in foreign countries, as the physicians do not seem to be as familiar with this disease as are the American physicians. It is said to be more prevalent here than in other countries for reasons not yet satisfactorily explained.

In as brief a manner as possible, the particular conditions and circumstances, in which a surgeon should be summoned in consultation will now receive consideration.

(1) In cases of the fulminating variety of appendicitis, in which the symptoms are always grave, and generally becoming worse from hour to hour to an alarming degree, it is scarcely possible to obtain surgical aid too early in the disease. An operation may, or may not, be necessary, according to the condition of the patient; but from the very nature of things, an experienced surgeon is the best able to decide that point. No one would think of operating upon a person while in a state of profound collapse. The proper treatment for one in that condition is hypodermic and rectal stimulation and external heat. If he cannot be rallied in that way, he certainly cannot be by an operation. Profound prostration, which differs from collapse in that the clammy sweats, cold extremities, flickering pulse and sighing respiration are lacking, may call imperatively for an immediate operation. By speedily relieving the system of the pent-up septic materials the vital powers are thus enabled to rally, and to regain their normal condition. Hence in these cases of sudden and severe seizure, you want all the aid you can get, and you want it at once. Don't wait till to-morrow.

It may be said here, that, contrary to what might be inferred from some writers of the present day, an operation, however early it may be performed, will not save every case of appendicitis. A small proportion of the victims of this disease will perish whatever may be the treatment, and however promptly and thoroughly it may have been adopted. Operations performed within twelve hours of the onset of appendicitis have failed to give the slightest relief. And yet this fact should not discourage early operations, when

they are indicated, for in very many instances the convalescence dates from the time of the operation. It is simply a reminder that too much must not be expected from surgical measures.

(2) The greater proportion of cases of appendicitis met with in ordinary practice will probably come under this head. The symptoms are moderate in severity at first, but steadily grow worse every twelve hours or so, with perhaps occasional remissions. These cases are often very deceptive. The patient does not seem to be very sick. With an occasional opiate, or perhaps without anything of the sort, he suffers little pain; and the attendants and friends are loath to believe that a serious, if not a dangerous, process is going on in the abdomen, until the vital powers are so exhausted that the patient's chances for recovery are very materially diminished.

In these cases I should strongly urge that the surgeon be called not later than the third day. Very likely the symptoms will be only of moderate severity at that time; but the consultant can form a much more correct and satisfactory idea of the character of the disease before its manifestations have reached the point of danger. He will also be better prepared to attack the case at the proper moment; in fact, he can choose his own time for interference. It is hardly possible to attach too much importance to this point. If the symptoms do not show marked amelioration by the third day, further counsel should be sought, not that an operation may be demanded at once, but that due preparations may be made, and that no time may be lost when time is important.

(3) A patient has a moderate attack of appendicitis. He is to all appearances improving, when without any definite reason, the symptoms are aggravated. He has a relapse, and has to make another start in his convalescence, only to experience the same chain of events sooner or later to prevent his recovery. The patient, and oftentimes the physician, is inclined to attribute these relapses to over-exertion, an error in diet, catching cold, etc. While these factors may occasionally act as exciting causes, yet the essential feature to be borne in mind is a damaged appendix.

Every exacerbation means an extension of the morbid process, and leaves the patient a little weaker and a little worse off, than he was before. The time may come when he fails to rally and he then becomes an invalid from chronic appendicitis.

These cases are not quite free from danger, and sound judgment is required to decide the proper period for interference. Each case must be managed according to its condition and peculiarities, yet it may be said, that, as a rule, two, or at most, three or four relapses, according to the severity, are sufficient to call for removal of the appendix. I presume that every surgeon feels that he has delayed action too long in occasional instances, but I have yet to meet one who has cause to regret a premature operation under these circumstances. It is better to err on the side of safety.

(4) No variety of appendicitis is more embarrassing to the attending physician, or to the consultant, than the following: A man is seized with a sharp attack of pain in the umbilical region, accompanied by tenderness. It knocks him out, so to speak, doubles him up, and sends him to bed. The symptoms may be severe enough to produce a moderate collapse. An opiate under the skin gives him complete relief for

several hours. Seen for the first time during this period, the patient seems to have little or nothing the matter with him. No pain nor tenderness, no disturbance of pulse or temperature. Everything is quiet under the sway of the "divine poppy." In many instances this lull in the symptoms is deceptive, as in from twelve to twenty-four hours they return with increased violence. This is usually the signal for calling the surgeon, and it goes without saying, that he should be prepared to operate at once if necessary.

(5) And, finally, we have the recurring cases of appendicitis to consider, which differ from the relapsing variety in the fact that patients are apparently well between the attacks. Recently a gentleman consulted the reader for the following symptoms: Five or six times during the past year, after a hearty meal he has been suddenly seized with a severe pain in the umbilical region, which gradually worked down into the vicinity of the appendix. The pain is accompanied by marked local tenderness and inability to stand erect. It lasts about twelve hours, but the tenderness persists for three or four days or even longer. He is weak and exhausted for several days — much more so than would be expected after an ordinary attack of colic or indigestion. This man is strong, robust, and is entirely well between these attacks. In the reader's opinion he is suffering from a mild form of recurring catarrhal appendicitis. Now comes the important question of treatment. Is an operation necessary, and if so, when shall it be performed? The temperament of the surgeon and of the patient is a factor in deciding these questions. If the attacks are increasing in frequency or in severity, there can be little doubt as to the necessity of an operation; and the sooner it is done the safer and better for the patient. On the contrary, if the intervals are increasing in length, and the symptoms becoming less severe and of shorter duration with each attack, it might be well to wait a while before resorting to a radical cure, as a certain number of these cases do eventually wear themselves out, so to speak, and entirely disappear, thus coming under the head of "appendicitis obliterans." In the opinion of the writer six attacks of appendicitis in one year, even if mild, are quite sufficient to justify an operation for the removal of the exciting cause.

Not a few physicians entertain the idea that there is no occasion for calling the surgeon until a tumor has formed, indicating that the inflammatory process is limited in extent and has ceased spreading. That this idea is erroneous and misleading, is abundantly proven by the fact that in very many cases no tumor is ever found, and yet the convalescence dates from the moment of operation. It is often impossible to detect a tumor, even when present, by reason of its depth in the pelvis, its shape and size, as well as the thickness and rigidity of the abdominal walls. The presence of a tumor does not of itself indicate an operation, nor does its absence preclude it. In fact, the indications for treatment are influenced very little by this symptom. A tumor shows the variety of the inflammatory processes going on in the peritoneal cavity, and also indicates the site of the incision. The plan of treatment is based upon other and more important factors in the condition of the patient. If he is growing steadily worse, radical means are called for, and the more rapid is the progress of the symptoms, the earlier are effective measures demanded.

In closing I can but repeat what has already been said, that from a surgical standpoint it seems wise and prudent that every case of appendicitis of any severity or duration should be seen in the early stages by one accustomed to operating for this affection, as well as to deciding the many difficult questions which are constantly arising throughout its course.

If the initiatory symptoms were severe; if they are steadily growing worse; if they relapse, or come to a stand-still; if the patient is sick, weak, irritable, impatient, restless; and especially if he cannot pass wind, or is inclined to nausea, vomiting, hiccup or delirium, — then I urge you to be vigilant and prompt in calling for surgical aid, for reasons already mentioned. You will never be criticised for calling it too early or too often. The serious character of the affection, the sudden onset, the insidious course, the rapid and unexpected variations, the startling collapses and excruciating pain liable to occur in this affection, as in almost no other, will protect you from these charges. And should the result be unfortunate, you and the friends will have the lasting satisfaction of knowing that you have done your whole duty in the matter, and are in no way responsible for the disastrous termination.

OBSERVATIONS ON BRAIN SURGERY SUGGESTED BY A CASE OF MULTIPLE CEREBRAL HEMORRHAGE.¹

BY GEORGE L. WALTON, M.D.,

Instructor in Neurology, Harvard University; Physician to Neurological Department, Massachusetts General Hospital.

AND W. A. BROOKS, JR., M.D.,

Demonstrator of Anatomy, Harvard University; Surgeon to Out-patient Department, Massachusetts General Hospital.

THE patient, a young woman, was out riding horse-back, when the horse became frightened and bolted, throwing the rider headlong, the right side of her head striking against the lower rail of a fence. She was picked up and carried home in an unconscious condition.

About four hours later, Dr. Brooks was called to see her. At that time she was lying on her back, perfectly unconscious, breathing quietly and with a pulse of about 100. The face was flushed, the pupils were equal, somewhat dilated and reacted slowly to light. There was partial paralysis of the left side of the face, and complete paralysis of the left arm and leg. She had vomited once or twice since the accident.

In the right mastoid region, extending upwards and backwards, was a swelling, pressure upon which caused marked restlessness. The patient was immediately taken to the Massachusetts General Hospital. While in the ambulance she became somewhat restless; the right arm and leg were continually tossed about and there was apparently some evidence of returning consciousness, such as indistinct mutterings. The pulse was rapid and varied in strength; the respirations were shallow. The face grew pale and the extremities cool. There was incontinence of urine.

She was admitted to the hospital about five P. M. The hospital record of her condition at that time is as

¹ Read before the Boston Society for Medical Improvement, December 28, 1896.

follows: Pupils equal, somewhat dilated and reacting slowly to light; paralysis of left side of the face; left arm flexed and rigid; left leg rigid and paralyzed; patella reflexes normal. Large hematoma covering the right mastoid region, extending well into the occipital and parietal. Pulse 96, of fair quality but of irregular rhythm; respiration about 24, normal in character. Pressure over the hematoma caused the patient to move the right arm and leg violently.

The scalp was shaved and an ice-bag applied. She was given one-sixth of a grain of elaterium.

During the night the patient became very restless; the right arm and leg were constantly in motion. The left hand was moved a little. There was incontinence of urine. Temperature at one A. M. (rectal) was 102.4°; the pulse varied from 100 to 130; the respiration from 20 to 30. Patient still unconscious.

Second day. In the morning the pulse was more steady and of better quality; the temperature (rectal) was 97.2°. The patient was still very restless, with constant tossing of the right arm and leg. The left arm was moved quite freely when the hematoma was pressed, though both the arm and leg were still somewhat rigid. The bowels were moved after a drachm of jalap powder and a suds and glycerine enema.

In the afternoon the left arm and leg were somewhat less rigid, and the patient groaned when the right side of the head was pressed, at one time making a slight attempt at articulation. Up to this time improvement had been apparent; but in the evening the patient had hardly held her own, the rigidity and paralysis of the left side were quite well marked, and no response was made upon efforts to arouse her. With the advice of Dr. Walton, who had been following the case, it was determined to make an exploratory opening.

OPERATION.

A curved incision was made, extending from the external angle of the right orbit to one inch above and behind the mastoid, and a semicircular flap turned downward. The temporal muscles and pericranium were retracted. The surface of the skull was found to be in perfect condition, with no evidence of fracture. A small trephine was applied about two and one-half inches above the external auditory meatus. On removal of the trephine button, it was noticed that the dura (which was tense and non-pulsating) was slightly nicked on account of its closer approximation to the skull. A quantity of clear serum escaped from the opening. The dura was incised, about half an ounce of clear fluid spouting through the incision. The brain appeared somewhat edematous, but otherwise normal. Exploration under the dura revealed no sign of hemorrhage. The opening in the dura was closed by fine silk sutures, the pericranium was sutured across, and the skin wound drawn together with stitches of silkworm gut.

Recovery from the ether was marked by great restlessness and a weaker and more variable pulse, rising at one time to 150. The left arm and leg again became rigid.

Third day. No particular change; patient very restless, with variable pulse. In the evening the respiration became stertorous. The left arm and leg moved somewhat, and were much less rigid than the day before. The patella reflex was absent. A little milk and lime-water was taken by the mouth. The bowels were moved by croton oil, and nutritive enemata

given. The wound was dressed in the afternoon and looked well. There was considerable serum on the dressing. One stitch was removed and a gauze wick inserted.

Fourth day. The patient passed a fairly comfortable night, seeming rather more conscious in the morning and responding more readily to stimulation. The eyes showed a tendency to roll up. Sordes gathered on the lips and teeth. Some improvement appeared in the character of the pulse and respiration, and there was more motion and less rigidity in the left arm and leg. The patella reflexes had returned. In the afternoon the patient seemed more conscious than in the morning, and made some response to questions. The pulse was 96, and the respiration 20. There was less restlessness and less facial paresis. There was still incontinence of urine, a symptom which persisted throughout.

Fifth day. The patient was very restless and noisy all day, delirious and muttering incoherently. The general appearance, however, was much better, and an attempt was apparently made to respond to questions. The left side was used much better, and there was little, if any, facial paralysis.

Sixth day. Improvement continued. The patient, though still delirious, was much more quiet. Milk and lime-water were taken by the mouth.

Seventh day. The patient was very quiet and drowsy most of the day, talking very little, but apparently understanding when spoken to. The whole appearance was more natural; the left side was moved freely.

Eighth day. No particular change. More nourishment taken by the mouth. Wound looks well.

Ninth day. Patient more quiet and somewhat harder to rouse. The stitches were removed and the wound found practically healed. The hematoma persisted. Over a quart of milk was taken during the day.

Tenth day. Unconsciousness was somewhat deeper, the patient being roused with difficulty. The hematoma was incised, and about half an ounce of dark blood expressed. The condition of the left side was about the same.

Eleventh day. Patient rather more easily roused to-day. The nutritive enemata were omitted, milk being taken freely by the mouth.

Twelfth day. Unconsciousness deeper. Rather more difficulty in swallowing appeared, but a quart of milk and several raw eggs were taken.

Fourteenth day. Patient less conscious and very quiet. No definite paralysis and no trace of rigidity in the left side, though comparatively little movement was made.

Fifteenth day. The temperature, pulse and respiration all rose suddenly; examination of the chest showing nothing abnormal excepting a few moist râles at the base. Strychnia, one-thirtieth of a grain, was ordered every three hours, subcutaneously, without any effect upon the pulse.

Sixteenth day. The patient has grown decidedly worse. The lungs are filling up. Oxygen, digitalis, and enema of salt solution produced no response. The patient died at 8.45 in the evening.

AUTOPSY, BY DR. WRIGHT.

Anatomical diagnosis: Trephination. Multiple cerebral hemorrhage with softening.

Body of tall, young woman. Slender build. Somewhat emaciated.

In scalp. Semicircular wound, nearly healed. Wound extended from right temporal region, over right parietal eminence, downward toward mastoid. Length of wound about twelve centimetres. Edges of wound adherent. No suppuration. Tissue in neighborhood of a dark-red color, evidently from diffused blood. In right mastoid region, subcutaneous tissue contained a flattened cavity about the size of a half-dollar.

In skull, in neighborhood of right parietal eminence, a circular hole, two centimetres in diameter. Through this the dura could be seen, with reddish exudation on its surface. On removing the calvarium, the dura was found to be moderately adherent, but there was no evidence of extra- or intra-dural hemorrhage. Exudation seen through the trephine opening did not extend any farther than the limits of the opening. There was no evidence of any fracture of the calvarium. The brain showed no evidence of meningeal hemorrhage, and externally showed nothing remarkable. On section, several hemorrhagic, softened areas were found in the following situations: In the left frontal, first convolution, about one centimetre from the surface, there was an ovoid area, the size of a common bean, of a dark, brownish-black color, soft consistency and indefinite margin. A similar area was also found in the white matter, about one centimetre anterior to the caudate nucleus. Another similar soft, dark brown area was found just beneath the floor of the right lateral ventricle, near the outer margin of the optic thalamus. In several places throughout the white substance of the brain, there were pin-head-sized, dark-brown areas which did not wash off. Careful inspection of the base of the skull revealed no fracture.

No cause of death was found in the viscera.

The atypical course of this case illustrates the difficulties occasionally encountered by surgeons and neurologists after blows and falls upon the head. The symptoms produced by meningeal hemorrhage, whether extra- or subdural, have been so fully illustrated and discussed of recent years that few surgeons would fail to recognize a typical case. The deepening unconsciousness passing into coma, with or without stertorous respiration, whether following directly the initial effects of the blow, or whether preceded by an interval of consciousness is certainly in itself suggestive of hemorrhage, and if accompanied by unilateral convulsions, paralysis, or both, the imperative demand for operation is generally recognized. It has even been noticed that this set of symptoms may be produced by a hemorrhage upon same side with the paralysis, an unusual condition, the pathology of which is obscure. Possibly in such cases we have to do with a failure of the pyramidal fibres to cross, or perhaps, as Dr. Putnam has suggested, the brain on the side of the hemorrhage becomes gradually accustomed to the pressure, but at a certain point the pressure on the other side becomes more sudden through edema and other pathological changes.

Whatever the pathology of this condition, this fact must be always borne in mind and the question considered, whether both sides should not be trephined in cases positively indicating hemorrhage, in case of failure to discover hemorrhage on the side of the brain opposite the convulsions or paralysis. One of the writers has had an opportunity to see this condition

verified by autopsy, in a case seen with Dr. Swan, of Cambridge.

Another condition had to be borne in mind in our case, namely, that severe concussion of the brain sometimes produces, especially in young women, a condition allied to hysteria, a trance-like state following the unconsciousness of concussion. In such cases, the unconsciousness, instead of gradually deepening, gradually lessens, though its prolongation for a week or even more may cause the attending surgeon great uneasiness and even seem to demand operation.

In the case under consideration, the fact that the patient winced and showed other signs of pain, when the hematoma was pressed upon, on the night following the injury, rendered it possible that there was an element of this sort in the case. The improvement in the mental condition during the following day did not tend to dispel this possibility although the one-sided paralysis excited considerable apprehension, for it must be remembered that meningeal hemorrhage is sometimes followed by paralysis without convulsions. It was decided, however, that should the improvement cease or the unconsciousness deepen, operation was imperative. In point of fact on the night following the accident the condition seemed distinctly worse, rendering operation advisable and even imperative, although the case did not run the typical course of hemorrhage.

The operation, as is seen by the report, proved negative, excepting that a certain amount of pressure, which had rendered the dura tense and prevented pulsation, was relieved by an unusual flow of cerebro-spinal fluid. The improvement caused by this relief of pressure was only temporary, and in the course of the following week the patient on the whole steadily lost ground, and one week from the operation elevation of temperature, pulse and respiration showed that the disturbance was becoming profound. At this time operation was considered by Dr. Porter, to whose service the patient had passed.
